## Smart hedging against carbon leakage

#### Abstract:

Unilateral climate policy induces carbon leakage through the relocation of emission-intensive and trade-exposed industries to regions with no or more lenient emission regulation. Both analytical and numerical studies suggest that emission pricing combined with border carbon adjustment is a second-best instrument, and more cost-effective than output-based rebating, in which case domestic output is indirectly subsidized. No country has so far imposed border carbon adjustment, while variants of output-based rebating have been implemented. In this paper we show that combining output-based rebating for emission-intensive and trade-exposed goods with a consumption tax on the same goods can be equivalent with border carbon adjustment. Moreover, we demonstrate that it is welfare improving for a region which has already implemented emission pricing along with output-based rebating with a consumption tax constitutes smart hedging against carbon leakage: Compared to output-based rebating stand-alone it constitutes a robust strategy for improving cost-effectiveness of unilateral climate policy; compared to border carbon adjustment it limits the risks of potentially detrimental trade disputes

Keywords: Carbon leakage; output-based rebating; border carbon adjustment; consumption tax

#### Sammendrag

Unilateral klimapolitikk kan lede til karbonlekkasje ved at utslippsintensiv og konkurranseutsatt industri flyttes til land med mindre streng regulering. Både analytiske og numeriske studier indikerer at karbonlekkasje kan dempes ved å kombinere en pris på utslipp med en karbontoll. Litteraturen indikerer også at karbontoll er mer kostnadseffektivt enn alternative virkemidler som produksjonsbasert refusjon av utslippsskatten eller gratis tildelte utslippskvoter.

Foreløpig har ingen land innført karbontoll, men ulike varianter av produksjonsbasert refusjon og utslippskvoter har blitt implementert. EU sitt kvotesystem er et godt eksempel på produksjonsbaserte gratiskvoter. Produksjonsbasert refusjon eller gratiskvoter utgjør en indirekte subsidie av produksjonen.

I denne artikkelen studerer vi en kombinasjon av produksjonsbasert refusjon (eller gratiskvoter) og en skatt på konsum av det samme godet. Vi viser at en slik kombinasjon kan ha samme virkning som en karbontoll. Videre viser vi at en slik ordning gir økt velferd, både for landet selv og for verden som helhet.

Vi konkluderer derfor med at kombinasjonen produksjonsbasert refusjon og skatt på konsum kan være et fornuftig virkemiddel for å dempe karbonlekkasje ved unilateral klimapolitikk. Sammenliknet med refusjon alene gir denne kombinasjonen økt kostnadseffektivitet og velferd. Sammenliknet med en karbontoll medfører kombinasjonen mindre risiko for potensiell uenighet med handelspartnere som kan oppfatte innføring av karbontoll som proteksjonisme.

## **1. Introduction**

In response to the threat of climate change, many countries consider or have introduced unilateral climate policies. However, greenhouse gases are global pollutants and unilateral action leads to carbon leakage, such as relocation of emission-intensive and trade-exposed (EITE) activities to countries with no or more lenient climate regulations. Unilateral constraints on emissions raise production costs for emission-intensive industries such as steel, cement, and chemical products, reducing their competitiveness in the world market, thereby inducing more production and emissions in unregulated regions.

To mitigate counterproductive leakage, countries have either exempted EITE industries from the regulation, or searched for supplemental anti-leakage measures. As a prime example, EITE industries in the EU, which are regulated under an emissions trading system (EU ETS), have received large amounts of free allowances. Currently, allowances are mainly allocated in proportion to installations' production. Free allowances have also been introduced in other emissions trading systems such as in New Zealand, South Korea and California, and in the regional emissions trading systems in China (World Bank, 2014). Free allowance allocation conditional on output can be interpreted as output-based rebating (OBR) of emission tax payments (e.g., Böhringer et al., 1998; Bernard et al., 2007).

Another potential anti-leakage measure that figures prominently in the economic literature is border carbon adjustment (BCA) with carbon tariffs on imports and rebates on exports of EITE goods. Most studies on carbon leakage suggest that BCA outperform OBR with respect to leakage reduction and cost-effectiveness of reducing global emissions (Monjon and Quirion, 2011a; Fischer and Fox, 2012; Böhringer et al., 2014a). BCA are however politically contentious, and experts differ in their views about whether or not it is compatible with WTO rules (see e.g. Horn and Mavroidis, 2011, Tamiotti, 2011, and Böhringer et al., 2012b).<sup>1</sup> One signal for its limited political feasibility is that – so far – border measures have only been proposed but not implemented.<sup>2</sup>

<sup>&</sup>lt;sup>1</sup> In 2010, the Indian Environment Minister threatened to "bring a WTO challenge against any 'carbon taxes' that rich countries impose on Indian imports" (ICTSD, 2010). There is also a fear that BCA could trigger a trade war (Holmes et al., 2011). On the other hand, Nordhaus (2015) argues that trade penalties can induce countries to join a "Climate Club" (see also Helm and Schmidt, 2015, and Böhringer et al., 2015).

<sup>&</sup>lt;sup>2</sup> For example, border measures have been included in the American Clean Energy and Security Act of 2009 that passed the U.S. Congress but not the Senate (see <u>https://www.congress.gov/bill/111th-congress/house-bill/2454;</u> Fischer and Fox, 2011). Border measures have also been put forward by the EU Commission (2009) as a possible future alternative to free allowance allocation.

Regarding economic incentives, a key difference between OBR and BCA is that whereas the latter dampens foreign supply of EITE goods to the regulated country, the former stimulates domestic production. The reason is that OBR acts as an implicit production subsidy (Böhringer and Lange, 2005). As a consequence, production and consumption of EITE goods will be too high under OBR, compared to second-best setting with BCA.<sup>3</sup> In other words, the incentives to switch from buying emission-intensive to less emission-intensive products are weakened under OBR. As demonstrated by Böhringer et al. (2014a), whereas BCA automatically becomes inactive as the coalition of regulating countries covers the whole world, OBR continues to stimulate too much output of the EITE goods. Similarly, whereas BCA for goods without trade exposure has little or no impacts, OBR triggers too much production.

In this paper we show that it is welfare improving for a country, that has already implemented a carbon tax (or an emissions trading system) along with OBR to EITE goods, to also impose a consumption tax on the same EITE goods. By consumption tax, we refer to product-specific taxes on all purchases of these goods, i.e., not only on final consumption but also on intermediate use in production. The intuition behind the welfare-improving effect of such a consumption tax is that OBR stimulates too much output of EITE goods. Note that in a closed economy OBR and the consumption tax cancel each other out, just as BCA become inactive in a closed economy. We also find that even in the case without any rebating, it is welfare improving to implement a consumption tax on EITE goods as it reduces foreign production (and hence emissions) of such goods.

The theoretical trade literature has established the result "that a combination of a production subsidy and a consumption tax at equal rates is tantamount to a tariff if the commodity is being imported, and an export subsidy if it is being exported" (Dixit 1985, p.356). Building on this fundamental idea we show that combining OBR with a consumption tax may be equivalent with BCA. The equivalence requires that the consumption tax for an EITE good is equal to the OBR rate, which in turn must equal the carbon tariff and the export rebate.<sup>4</sup> To our best knowledge, this equivalence result has not been shown so far in the context of emission leakage.<sup>5</sup>

<sup>&</sup>lt;sup>3</sup> This conclusion may no longer hold in the case of pre-existing market imperfections such as market power, see e.g. Gersbach and Requate (2004).

<sup>&</sup>lt;sup>4</sup> All instruments are applied in monetary value per unit of the EITE good. For instance, with 100% rebating, i.e., all emission payments from an EITE industry are rebated back to the industry in proportion to firms' output, the equivalence requires that the carbon tariff is based on domestic emission intensities, and that there is 100% export rebating.

<sup>&</sup>lt;sup>5</sup> In a somewhat similar context with trade in a homogenous fossil fuel good, Hoel (1994) notes that a climate coalition can improve its terms-of-trade in the fuel market by either introducing an import (export) tariff or a combination of production subsidy (tax) and consumption tax (subsidy) if the coalition is a net importer (exporter) of fossil fuels.

For unilateral climate policy design, our finding suggests a viable alternative to contentious BCA, thereby lowering the risk of potentially detrimental trade wars. From a practical point of view, there are no extra administrative costs in determining the consumption taxes as long as benchmarks are already determined for the OBR rates (such as the benchmarks currently used in the EU ETS).

We substantiate our analytical findings with complementary numerical results based on a stylized computable general equilibrium (CGE) model with two regions and four goods, where the goods can be either consumed or used as intermediate input into production. The numerical results are in accordance with our analytical findings. In addition, the simulations demonstrate that the advantage of a consumption tax becomes particularly relevant if the EITE good produced domestically cannot be easily substituted by foreign goods. In this case the potential for leakage is limited, and thus the distortive effects of stimulating output are getting more critical. By combining OBR with a consumption tax, the distortive effect of OBR can be controlled for. Such a hedging strategy becomes particularly policy-relevant if there is uncertainty about leakage exposure for individual sectors. The actual practice in EU climate policy sheds some light on the issue at stake. In the EU ETS, sectors that are "exposed to a significant risk of carbon leakage" receive a high share of free allowances.<sup>6</sup> A majority of industry sectors have been put into this group. In contrast, Sato et al. (2015) find that "vulnerable sectors account for small shares of emission", and Martin et al. (2014) conclude that the current allocation results in "substantial overcompensation for given carbon leakage risk". Note that supplementing OBR with a consumption tax does not only provide a hedge against uncertainty on data grounds but also with respect to lobbying activities by industries.

There is a large body of literature on carbon leakage. The seminal paper by Markusen (1975) derives the first-best combination of a domestic emission tax and a tariff on imported goods (in his model, emissions are functions of production only), where the optimal tariff depends on both leakage and terms-of-trade effects. In a similar vein, Hoel (1996) determines an optimal combination of an emission tax and a carbon tariff (or export subsidy), where he also includes the indirect emission effects of the tariff (see also Copeland, 1996, for an early analytical contribution).

Many numerical modeling studies quantify carbon leakage, the bulk of them using multi-region and multi-sector CGE models of the world economy. For policy-relevant parameters on key dimensions – such as the stringency of emission regulation or the size of the abatement coalition – most studies conclude that the leakage rate of a unilateral carbon tax (or emissions trading) is in the range of 5-

<sup>&</sup>lt;sup>6</sup> <u>http://ec.europa.eu/clima/policies/ets/cap/leakage/index\_en.htm</u>

30%, i.e., a reduction of 100 units of CO<sub>2</sub> in the regulating country leads to an increase of 5-30 units of CO<sub>2</sub> in non-regulating countries (see, e.g., the review by Zhang, 2012, and the special issue edited by Böhringer et al., 2012a). There are, however, a few outliers with negative leakage (Elliott and Fullerton, 2014) or leakage rates above 100% (Babiker, 2005), adopting less conventional assumptions on international factor mobility or market power. Studies that calculate leakage from single EITE industries often find somewhat higher leakage rates (e.g., Ponssard and Walker, 2008, and Fischer and Fox, 2012) since competitiveness losses get relatively more pronounced.

Leakage mainly occurs through two intertwined channels. In this paper we focus on leakage through the market for EITE goods, often referred to as the competitiveness channel. The second channel is the so-called fossil-fuel channel: Reduced demand for fossil fuels in climate policy regions depresses international fuel prices, stimulating fuel consumption and thus emissions in other regions (Felder and Rutherford, 1993). The policy debate focuses on leakage through the competitiveness channel, mirroring concerns of regulated EITE industries on adverse competitiveness effects. The policy focus goes also along with broader scope of policy options – such as BCA or OBR – to mitigate leakage through EITE markets rather than leakage through fossil fuel markets.

Our paper also relates to a strand of literature that examines consumption taxes in environmental regulation, either alone or in combination with other instruments. In particular, Holland (2012) shows that adding a consumption tax to an emission intensity standard can improve efficiency of unilateral climate policy, as standards trigger inefficiently high consumption. Tradable intensity targets can be re-interpreted as a combination of an emission price and OBR – in this respect, Holland's finding is comparable with our result on the efficiency gains through supplemental consumption taxes. However, Holland's model includes only one good, with domestic and foreign goods being homogenous, whereas we use a model with three goods, with domestic and foreign goods being either homogenous or heterogeneous. Eichner and Pethig (2015a) examine consumption-based taxes as an alternative to emission (production-based) taxes in a two-period two-country analytical general equilibrium model with a finite stock of fossil fuels, concluding that consumption-based taxes may reduce the cost of unilateral climate policy. In follow-up work, Eichner and Pethig (2015b) show that a combination of production-based taxes outperform production-based taxation stand-alone.

The remainder of this paper is organized as follows. In Section 2 we lay out our theoretical model and analyze the optimal consumption tax in a situation where an emission tax combined with OBR is already in place; we then demonstrate the equivalence between BCA and the combination of OBR and

consumption tax. In Section 3, we develop a stylized computable general equilibrium model calibrated to empirical data for the world economy and substantiate our analytical results with numerical simulations. Section 4 concludes.

## 2. Analytical model

We consider a model with two regions,  $j = \{1,2\}$ , and three goods *x*, *y* and *z*. Good *x* is emission-free and tradable, good *y* is emission-intensive and tradable, while good *z* is emission-intensive and nontradable.<sup>7</sup> Same goods produced in different regions are assumed to be homogenous,<sup>8</sup> with no trade cost (for the two tradable goods). We interpret *y* as emission-intensive and trade-exposed (EITE) sectors where output-based rebating is considered (e.g., chemicals, metal and other mineral production), and *z* as sectors where leakage is of less concern (e.g. electricity production and transport). The market prices (excluding taxes) of goods *x*, *y* and *z* in region *j* are denoted  $p^{xj}$ ,  $p^{yj}$  and  $p^{zj}$ , respectively.

The representative consumer's utility from consumption in region *j* is given by  $u^j(\tilde{x}^j, \tilde{y}^j, \tilde{z}^j)$ , where

 $\tilde{x}^{j}$ ,  $\tilde{y}^{j}$  and  $\tilde{z}^{j}$  denote consumption of the three goods. The utility function is twice differentiable, increasing and strictly concave; i.e., we have  $u_{x}^{j} \equiv \partial u^{j} / \partial x^{j} > 0, u_{y}^{j} > 0, u_{z}^{j} > 0$  and the Hessian matrix is negative definite.

Production of good x in region j is  $x^{j} = x^{1j} + x^{2j}$ , where  $x^{ij}$  denotes goods produced in region j and sold in region i. We use similar notation for good y. The market equilibrium conditions are then:

(1)  
$$x^{1} + x^{2} = \widetilde{x}^{1} + \widetilde{x}^{2}$$
$$y^{1} + y^{2} = \widetilde{y}^{1} + \widetilde{y}^{2}$$
$$z^{j} = \widetilde{z}^{j}$$

Cost of producing good *x*, *y* and *z* in region *j* is given by  $c^{xj}(x^j)$ ,  $c^{yj}(y^j, e^{yj})$  and  $c^{zj}(z^j, e^{zj})$ , respectively, with  $e^{yj}$  and  $e^{zj}$  denoting emissions. We assume that cost is increasing in production for

<sup>&</sup>lt;sup>7</sup> Note that we use emission(-intensive) and carbon(-intensive) interchangeably throughout the text, as we want to adhere to the established terms "emission-intensive and trade-exposed (EITE)" and "border carbon adjustment (BCA)".

<sup>&</sup>lt;sup>8</sup> Thus, only net trade matters for each good in this model. In Appendix A we show that our results generalize to heterogeneous goods (see Corollary 3), and in the simulations in Section 3 we consider both homogenous and heterogeneous goods.

all goods, and that cost of producing y and z is decreasing in emissions; more precisely,  $c_x^{xj}, c_y^{yj}, c_z^{zj} > 0$ and  $c_e^{yj}, c_e^{zj} \le 0$ , with strict inequality when emissions are regulated. Further, cost is assumed to be twice differentiable and strictly convex. Last, all derivatives are assumed to be finite.

#### 2.1 Output-based rebating and consumption tax

For our analysis we assume that region 1 undertakes unilateral emission regulation and disposes of three policy instruments (variables): an emission tax  $t^1$ , an output subsidy  $s^1$  to production of good y, and a consumption tax  $v^1$  on buying good y. Without uncertainty, output-based rebating (OBR) is equivalent with an output subsidy, where the subsidy is linked to the emission tax. In particular, if the tax revenues are fully redistributed back to the producers, the implicit subsidy of OBR is  $s^1 = t^1 e^{y_1} / y^1$ , a case we will refer to as 100% OBR.<sup>9</sup> We assume no climate policy in region 2, i.e.,  $t^2 = s^2 = v^2 = 0$ .

Competitive producers in region *j* maximize profits:

$$\max_{x^{1j}, x^{2j}} \left[ p^{x_1} x^{1j} + p^{x_2} x^{2j} - c^{xj} (x^j) \right]$$
  
$$\max_{y^{1j}, y^{2j}, e^j} \left[ \left( p^{y_1} + s^j \right) y^{1j} + \left( p^{y_2} + s^j \right) y^{2j} - c^{yj} (y^j, e^{yj}) - t^j e^{yj} \right].$$
  
$$\max_{z^j} \left[ p^{zj} z^j - c^{zj} (z^j, e^{zj}) - t^j e^{zj} \right]$$

This gives the following first-order conditions for an interior solution:

(2)  

$$p^{x1} = p^{x2} = c_x^{x1} = c_x^{x2}$$

$$p^{y1} + s^1 = p^{y2} + s^1 = c_y^{y1} ; \quad p^{y1} = p^{y2} = c_y^{y2}$$

$$p^{zj} = c_z^{zj}$$

$$c_e^{y1} = c_e^{z1} = -t^1 ; \quad c_e^{y2} = c_e^{z2} = 0$$

Note that an interior solution requires that there is one global price for each of the tradable goods x and y, as both goods are homogenous with no trade cost (this is not the case with heterogeneous goods, see Corollary 3 and the proof in Appendix A). The domestic emission tax  $t^{l}$  induces higher cost of producing good y in region 1, which implies higher output and emissions in region 2 through the

<sup>&</sup>lt;sup>9</sup> Most studies of OBR in the literature consider 100% rebating. In the EU ETS, the most leakage-exposed industries, accounting for more than half of total emissions from installations that receive free allowances, have around 100% rebating on average. Note that this does not mean that the allowances they receive cover all their needs, as  $e^{v^1}$  in the expression above denotes regulated emissions, which typically are lower than baseline emissions. Meunier et al. (2014) argue that the allocation mechanism in the EU ETS may be better characterized by capacity-based allocation, as new (and expansion of existing) installations receive allowances in proportion to their installed capacity.

international market for good y. The motivation for the subsidy  $s^{l}$  (or OBR) is to target this leakage by driving a wedge between marginal production cost in region 1 and the market price on good y, and hence to stimulate domestic output of this good. The net effect of  $t^{l}$  and  $s^{l}$  on  $y^{1}$  is ambiguous. The representative consumer in region *j* maximizes utility, given consumer prices and a budget restriction. After constructing the Lagrangian function and then differentiating, we get the following first-order conditions:

(3) 
$$u_x^j = p^{x^j}, u_y^j = p^{y^j} + v^j, u_z^j = p^{z^j}.$$

We assume that the regions have a balance-of-payment constraint, so that import expenditures must equal export revenues in both regions. Net export for region *j* is equal to production minus

consumption in that region, i.e.,  $x^{j} - \tilde{x}^{j}$  and  $y^{j} - \tilde{y}^{j}$ . Using  $p^{y_{1}} = p^{y_{2}} \equiv p^{y}$  and  $p^{x_{1}} = p^{x_{2}} \equiv p^{x}$  from the first-order conditions in (2), we have:

(4) 
$$p^{y}\left(y^{j}-\tilde{y}^{j}\right)+p^{x}\left(x^{j}-\tilde{x}^{j}\right)=0$$

#### 2.2 The optimal consumption tax under OBR

#### Regional welfare maximization

We now want to derive the optimal consumption tax on good y in region 1, given that the region has already implemented an emission tax  $(t^1)$  on goods y and z, combined with OBR  $(s^1)$  to good y. Welfare in region 1 is given by:

(5) 
$$W^{1} = u^{1}(\tilde{x}^{1}, \tilde{y}^{1}, \tilde{z}^{1}) - c^{x^{1}}(x^{1}) - c^{y^{1}}(y^{1}, e^{y^{1}}) - c^{z^{1}}(z^{1}, e^{z^{1}}) - \tau(e^{y^{1}} + e^{y^{2}} + e^{z^{1}} + e^{z^{2}}),$$

where  $\tau$  is the shadow cost of emissions, i.e., the Pigouvian tax. We assume that emissions abroad are valued by the same shadow cost as emissions at home. This is a reasonable assumption for greenhouse gas emissions, with spatially independent emissions damage. We then have the following result:

**Lemma 1.** Let welfare in region 1 be given by equation (5), and assume that the emission tax is set equal to the Pigouvian tax, i.e.,  $t^1 = \tau$ . Then the welfare maximizing consumption tax  $v^{l^*}$  on good y is given by:

(6) 
$$v^{1*} = \left(\underbrace{\frac{\partial \tilde{y}^{1}}{\partial v^{1}}}_{(a)}\right)^{-1} \left[\underbrace{\underbrace{s^{1} \frac{\partial y^{1}}{\partial v^{1}}}_{(b)} + \tau \left(\underbrace{\frac{\partial e^{y^{2}}}{\partial y^{2}} \frac{\partial y^{2}}{\partial v^{1}}}_{(c)} + \underbrace{\frac{\partial e^{z^{2}}}{\partial z^{2}} \frac{\partial z^{2}}{\partial v^{1}}}_{(d)}\right) - \underbrace{\frac{\partial p^{y}}{\partial v^{1}} \left(y^{1} - \tilde{y}^{1}\right) - \frac{\partial p^{x}}{\partial v^{1}} \left(x^{1} - \tilde{x}^{1}\right)}_{(e)}\right]}_{(e)}$$

#### **Proof.** See Appendix A.

The first factor (*a*) in (6) is negative, as a higher consumption tax on good *y* in region 1 reduces consumption of this good in that region (see Appendix A). Hence, the sign of  $v^{1*}$  is the opposite of the sign of the square bracket.

Inside the square bracket the first term (b) is negative, as reduced demand for good y in region 1 reduces the market price of y and hence output of good y in both regions. This term reflects that the OBR-subsidy, which reduces leakage through depressing foreign production, has a negative side effect as it leads to too much consumption (marginal production cost in region 1 exceeds the consumer price in both regions). The optimal consumption tax corrects for this.

The two next terms capture emission effects in region 2, which abstains from emission regulation. Term (*c*) is negative by the same reasoning as for term (*b*), and the fact that emissions are increasing in output. The sign on term (*d*) is a priori ambiguous and depends on the cross derivatives of the utility function in region 2, in particular whether *z* is a complement or a substitute to good *y*. As the consumption tax reduces the price of *y*, consumption of this good in region 2 increases. This will tend to reduce the consumption of other goods, and hence production of the non-tradable *z* good, in region 2 unless *y* and *z* are complements (in consumption). Moreover, because *z* is typically dominated by electricity generation and transport, and electricity is an important input into production of many EITE goods, reduced output of *y* in region 2 will also tend to decrease consumption (and thus production) of *z*. For these two reasons, we find it likely that the sign of  $\partial z^2 / \partial v^1$  is negative. In any case, it is very likely that this second-order effect is dominated by the first-order effect (*c*). We will henceforth make the following assumption:

(7) 
$$\frac{\partial e^{y^2}}{\partial y^2} \frac{\partial y^2}{\partial v^1} + \frac{\partial e^{z^2}}{\partial z^2} \frac{\partial z^2}{\partial v^1} < 0$$

which of course is always true if  $\partial z^2 / \partial v^1 < 0$ .<sup>10</sup>

<sup>&</sup>lt;sup>10</sup> In the simulations in Section 3, the sign of  $\partial z^2 / \partial v^1$  is consistently negative.

The last term (*e*) captures terms-of-trade effects. Whereas the price of good  $y(p^y)$  decreases, the price of good  $x(p^x)$  will increase due to increased demand. If region 1 is initially a net importer (exporter) of good y and net exporter (importer) of good x, both last terms are negative (positive). Note that the balance of payments constraint (4) requires that if region 1 imports good y, it must export good x (and vice versa). Hence, we have shown the following result:

**Proposition 1.** Consider a region that combines a Pigouvian tax on emissions with a subsidy to production of an emission-intensive, tradable good y, and considers a consumption tax on good y. Then we have:

- The optimal consumption tax on good y is unambiguously positive if the region is not a net exporter of good y.
- If the region is a net exporter of good y, then the optimal consumption tax on good y is positive if and only if the disadvantageous terms-of-trade effects are dominated by the beneficial effects from reducing excessive production of good y and emissions abroad.

**Proof.** *The proposition follows from equations (4), (6) and (7).* 

#### Global welfare maximization

So far, we have assumed that region 1's policy objective when setting the consumption tax is to maximize welfare in region 1. To assess unilateral climate policy design from a global welfare perspective, we consider the case where region 1 is concerned about effects on global welfare, including the cost of emissions as before.<sup>11</sup> Global welfare is:

(8) 
$$W^{G} = \sum_{j=1,2} \left[ u^{j} (\tilde{x}^{j}, \tilde{y}^{j}, \tilde{z}^{j}) - c^{xj} (x^{j}) - c^{yj} (y^{j}, e^{yj}) - c^{zj} (z^{j}, e^{zj}) - \tau (e^{yj} + e^{zj}) \right].$$

The consumption tax  $v^{1**}$  that maximizes global welfare (8) is given by (see Appendix A):

(9) 
$$v^{1^{**}} = \left(\frac{\partial \tilde{y}^{1}}{\partial v^{1}}\right)^{-1} \left[s^{1} \frac{\partial y^{1}}{\partial v^{1}} + \tau \left(\frac{\partial e^{v^{2}}}{\partial y^{2}} \frac{\partial y^{2}}{\partial v^{1}} + \frac{\partial e^{z^{2}}}{\partial z^{2}} \frac{\partial z^{2}}{\partial v^{1}}\right)\right] > 0$$

. 1

We observe that equation (9) is equal to equation (6) when terms-of-trade effects are zero. Thus, we have the following result:

<sup>&</sup>lt;sup>11</sup> For example, in Böhringer et al. (2014a), a coalition of countries concerned about leakage chooses the policy that maximizes global welfare. Böhringer et al. (2014b) decomposes leakage and terms-of-trade motives of differential sector-specific emission pricing, as such pricing can be used as a "beggar-thy-neighbor policy" to exploit terms of trade.

**Proposition 2.** Consider a region that combines a Pigouvian tax on emissions with a subsidy to production of an emission-intensive, tradable good y. If the regulator in this region maximizes global welfare, then the optimal consumption tax on good y in this region is unambiguously positive.

#### **Proof.** *The proposition follows from equations (7) and (9).*

There are some special cases worth elaborating on. To simplify the discussion, we focus on the global welfare perspective in Proposition 2 and equation (9), in which case there is no terms-of-trade effect. First, the optimal consumption tax on good *y* obviously increases in the OBR subsidy  $s^1$ . However, we also observe that the tax is unambiguously positive also without OBR (i.e.,  $s^1 = 0$ ). The reason is that reduced domestic demand for good *y* reduces imports of *y*, and hence reduces environmental damages from emissions abroad (emissions at home are already accounted for by the emission tax). Thus, in the case where region 1 has implemented (only) a Pigouvian tax, the region should also tax consumption of emission-intensive, tradable goods. We state this finding in the following corollary:<sup>12</sup>

**Corollary 1.** Consider a region that has implemented a Pigouvian tax on emissions. Then the optimal consumption tax on an emission-intensive, tradable good y is unambiguously positive if the regulator in region 1 maximizes global welfare.

#### **Proof.** The corollary follows from the discussion above.

Next, we see from equation (9) that if production and consumption in region 2 is unaffected by the consumption tax in region 1, e.g. because of no trade between the two regions, the optimal consumption tax is equal to the OBR subsidy, i.e.,  $v^{1**} = s^1$ . It follows that if domestic production and consumption change much more than foreign production and consumption, the optimal consumption tax is close to the OBR-rate. This could be the case if region 1 is much bigger than region 2.

The reason for this result is that the motivation for OBR is to mitigate emission leakage (and loss in competitiveness) induced by unilateral emission regulation. However, the effects of this policy are not only to shift market shares towards the domestic firm, but also to stimulate excessive use of this good. Therefore, the regulator would want the consumption tax to reduce the demand for good *y*. In this special case, when impacts in region 2 are negligible compared to in region 1, the optimal consumption tax completely offsets the distortion to the economy caused by the OBR subsidy. The intuition is straightforward: leakage is not an important issue when the domestic region is much larger

<sup>&</sup>lt;sup>12</sup> A similar result is found by Eichner and Pethig (2015b), who demonstrate that a combination of production-based (i.e., emission) and consumption-based taxes is less expensive than a production-based tax alone.

than the foreign region. Hence, introducing OBR is not a good idea in the first place, and the optimal consumption tax negates the effects of OBR.

The same result holds if the size of region 2 is more comparable with region 1, but both production and consumption in region 2 are insensitive to the climate policy in region 1. In our model with homogenous goods, this would be the case if, e.g., both the marginal cost and marginal utility for good y in region 2 are very steep. In a model with heterogeneous goods (see the numerical analysis in Section 3), the substitution elasticities between domestic and foreign goods are also important for how sensitive foreign consumption and production are to the domestic climate policy.

In policy practice, it may be difficult to determine how exposed a sector really is to leakage and, correspondingly, whether or not it should be included in an OBR regime. The above results suggest that a policy which combines OBR with a consumption tax is more robust with respect to uncertainties about leakage than OBR alone. The reason is that, because the consumption tax offsets the distortive effects of the output subsidy, the negative consequences of including too many sectors in an OBR-regime are reduced when the consumption tax is added.

Another policy-relevant special case is 100% OBR, i.e.,  $s^1 = t^1 e^{y_1} / y^1$  (see above). Given a Pigouvian emission tax ( $t^1 = \tau$ ), this implies  $\tau = s^1 y^{e_1} / e^1$ . To simplify the line of reasoning, we first assume that the average emissions intensity of good y in region 1 is equal to the marginal emissions intensity in region 2, i.e.,  $e^{y_1} / y^1 = \partial e^{y_2} / \partial y^2$ . Equation (9) then becomes (using the market equilibrium for y):

$$v^{1^{**}} = \left[1 + \left(\frac{\partial \tilde{y}^{1}}{\partial v^{1}}\right)^{-1} \frac{\partial \tilde{y}^{2}}{\partial v^{1}} + \left(\frac{\partial \tilde{y}^{1}}{\partial v^{1}}\right)^{-1} \frac{y^{1}}{e^{y^{1}}} \frac{\partial e^{z^{2}}}{\partial z^{2}} \frac{\partial z^{2}}{\partial v^{1}}\right] s^{1}$$

We know that consumption in region 1 decreases and consumption in region 2 increases in the consumption tax in region 1. Hence, the sum of the two first terms inside the square bracket is less than one. Thus, if  $\partial z^2 / \partial v^1$  is positive or sufficiently small in absolute value, we have  $v^{1**} < s^1$ . That is, contrary to the first special case, the regulator does not wish to completely offset the OBR subsidy, because the tax also stimulates consumption in region 2. For instance, if the tax only shifts consumption from region 1 to region 2, with no net effects on production, the tax has no impact on emissions and the optimal consumption tax is zero. More generally, the more the consumption tax is able to reduce overall production rather than shifting consumption abroad, the higher should the tax be.

On the other hand, it may be more reasonable to assume  $e^{y_1} / y_1 < \partial e^{y_2} / \partial y_2$ , as the emission tax will reduce the emission intensity in region 1. Hence,  $v^{1**}$  is not necessarily lower than  $s^1$ , and could exceed the subsidy if the emissions intensity in region 2 is significantly higher than in region 1 *and* the consumption tax affects global production more than consumption in region 2. In the simulations in Section 3, the optimal consumption tax is in the range 80-100% when global welfare is maximized.

# 2.4 Equivalence between border carbon adjustment and OBR with consumption tax

In this subsection we show that the combination of OBR and consumption tax on good *y* is equivalent to a certain specification of border carbon adjustment (BCA) on good *y* (assuming that the same emission tax is in place). Let  $\pi^1$  denote the carbon tariff on imports of good *y* to region 1, and let  $\gamma^1$  denote the export rebate to exports of good *y* from region 1. We still assume no climate policy in region 2, so that  $\gamma^2 = \pi^2 = t^2 = 0$ .

A carbon tariff is an import tariff on the embodied carbon in the imported good, proportional to the emission price in the importing region. Ideally, the tariff should reflect the emission intensity of the exporting firm, giving this firm an incentive to reduce emissions. However, such a system may be difficult and costly to implement, and hence analysis of carbon tariffs usually assume that the tariff is determined based on some average emission intensity. This average can either be the average emission intensity in the exporting region (which could be differentiated across regions if there were more than one export region), or the average emission intensity in the importing region.<sup>13</sup> Ismer and Neuhoff (2007) and Monjon and Quirion (2011b) argue that non-differentiated tariffs are more likely to be compatible with the WTO rules, and this is what we consider here. Furthermore, we base the tariff on the emission intensity in the import region, i.e.,  $\pi^1 = t^1 e^{y_1} / y^1$ . Export rebates under BCA proposals are usually set equal to  $\gamma^1 = t^1 e^{y_1} / y^1$ , so the export rebate and the carbon tariff are equal in this case. Moreover, we notice that  $\gamma^1 = \pi^1 = s^1$  in the case of 100% OBR.

The maximization problems for producers of goods x and z under BCA are equal to the OBR case. Hence, their first-order conditions are as given in equation (2). Producers of good y in region j maximize profits:

$$\max_{y^{1j}, y^{2j}, e^{j}} \left[ \left( p^{y^{1}} - \pi^{i} \right) y^{1j} + \left( p^{y^{2}} + \gamma^{j} \right) y^{2j} - c^{yj} (y^{j}, e^{yj}) - t^{j} e^{yj} \right],$$

<sup>&</sup>lt;sup>13</sup> Both these variants are examined in the literature (see, e.g., Böhringer et al., 2012b; Kuik and Hofkes, 2010; and Mattoo et al., 2009).

where  $i \neq j$ . This gives the following first-order conditions for an interior solution:

(10) 
$$p^{y^{1}} = p^{y^{2}} + \gamma^{1} = c_{y}^{y^{1}} ; \quad p^{y^{1}} - \pi^{1} = p^{y^{2}} = c_{y}^{y^{2}} - c_{e}^{y^{1}} = t^{1} ; \quad c_{e}^{y^{2}} = 0$$

For producers in region 1, the net price home and abroad are  $p^{y_1}$  and  $p^{y_2} + \gamma^1$ , respectively, while for producers in region 2, the net price home and abroad are  $p^{y_2}$  and  $p^{y_1} - \pi^1$ , respectively. An interior solution requires equal net prices on exports and domestic sales, implying  $p^{y_1} = p^{y_2} + \gamma^1$  and  $p^{y_2} = p^{y_1} - \pi^1$ . That is, the price in region 1 must exceed the price in region 2 by the amount  $\gamma^{y_1} = \pi^1$ . Notice that if we had specified the carbon tariff differently, so that  $\gamma^1 \neq \pi^1$ , we would not have an interior solution in this model with homogenous goods.<sup>14</sup>

The consumer utility maximization problem is similar as under OBR and a consumption tax, but with  $v^{j} = 0$  in (3). The budget constraint under BCA is still given by equation (4), where  $p^{y}$  denotes the international price of good y and also the price in region 2 ( $p^{y} \equiv p^{y^{2}}$ ). The first-order conditions for good y in (2), (3) and (10) may then be rewritten as in Table 1.

	OBR+Consumption Tax	BCA
Production	$p^{v} + s^{1} = c_{v}^{v^{1}}$ ; $p^{v} = c_{v}^{v^{2}}$	$p^{v} + \gamma^{1} = c_{y}^{v1}$ ; $p^{v} = c_{y}^{v2}$
Abatement	$-c_e^{v_1} = t^1$ ; $c_e^{v_2} = 0$	$-c_e^{y_1} = t^1$ ; $c_e^{y_2} = 0$
Consumption	$u_{y}^{1} = p^{y} + v^{1}$ ; $u_{y}^{2} = p^{y}$	$u_{y}^{1} = p^{y} + \pi^{1}$ ; $u_{y}^{2} = p^{y}$

Table 1. First-order conditions for good y under unilateral regulation

In addition, equilibrium requires the market equilibrium condition (1) and the budget constraint (4) to hold under both types of regulation. It is also straightforward to see that net government revenues are the same in the two cases.

We then have the following result:

<sup>&</sup>lt;sup>14</sup> In a model with heterogeneous goods, interior solution is feasible also when the carbon tariff deviates from the export rebate. However, equivalence still requires that these are identical, see (the proof of) Corollary 3 and the numerical analysis in Section 3.

**Proposition 3.** The two types of regulation i) emission tax with OBR and consumption tax, and ii) emission tax with BCA as specified above, induce equal production, consumption and emissions in both regions if  $v^1 = s^1 = \pi^1 = \gamma^1$ .

**Proof.** According to Table 1, all first-order conditions for good y are equal. Moreover, first-order conditions (2) and (3) for the goods x and z are equal, too. Market equilibrium conditions and budget constraints for all goods are given by equations (1) and (4), respectively, in both cases. The second-order conditions put identical constraints on the cost and utility functions under both types of regulations. The proposition follows.

Proposition 3 implies that under certain conditions, combining output-based rebating with a consumption tax has the same effect as full border carbon adjustment. As BCA is regarded as more contentious, though more effective than OBR, combining OBR with a consumption tax can be a viable policy alternative to implementing BCA.

In the discussion leading up to Proposition 3, we assumed that the carbon tariff is determined based on the emission intensity in region 1. However, it is straightforward to see that the proposition also may hold for different levels of carbon tariffs, *given that the export rebate is equal to the tariff.* Then by adjusting the OBR rate and the consumption tax accordingly, the equivalence still holds. The only requirement is that  $v^1 = s^1 = \gamma^1 = \pi^1$ . Thus, if the regulator in region 1 would like to impose a higher carbon tariff (and export rebate) than the one following from the domestic emission intensity, e.g., because emission intensities abroad are higher than at home, the same result can be achieved by imposing a combination of OBR and consumption tax. We state this generalization as a separate corollary:

**Corollary 2.** The two types of regulation i) emission tax with OBR and consumption tax, and ii) emission tax with BCA, are equivalent for any level of carbon tariff as long as  $v^1 = s^1 = \pi^1 = \gamma^1$ .

#### **Proof.** *The proof follows from the proof of Proposition 3.*

Whereas the motivation for OBR and BCA typically is to mitigate carbon leakage through the international product markets, the assumption that the good y is homogeneous and independent of region of origin is unrealistic for many emission-intensive and trade-exposed goods. Moreover, with several EITE goods exposed to leakage, these will typically have different carbon tariffs in a BCA system. It is straightforward to show that the propositions above carry over to the case with several

heterogeneous EITE-goods. For the equivalence result in Proposition 3, this requires that the outputbased rebating is good specific, i.e., emission payments from the production of one specific good is rebated back to producers of this specific good. We states these findings in the following corollary:

**Corollary 3.** Consider the case with  $m = \{1, 2, ..., M\}$  EITE goods denoted  $y_m$ , where each good is produced in both regions, and goods produced in different regions are imperfect substitutes. Then we have the following:

- The optimal consumption tax on good y<sub>m</sub> is unambiguously positive if the regulator in region 1 maximizes global welfare.
- The two types of regulations i) emission tax with OBR and consumption tax, and ii) emission tax with BCA as specified above, are equivalent if  $v^1 = s^1 = \pi^1 = \gamma^1$ .<sup>15</sup>

#### **Proof.** See Appendix A.

In the numerical simulations below we will consider both homogenous and heterogeneous EITEgoods, but restrict ourselves to the case with one EITE-good in each region.

### **3. Stylized Numerical Analysis**

We transfer our theoretical analysis to numerical simulations with a stylized computable general equilibrium (CGE) model to accommodate more functional (real-word) complexity to gain insights into the magnitude of economic effects based on empirical data. Below we first summarize the main characteristics of the numerical model in a non-technical manner (see Appendix B for an algebraic model summary). We then discuss the parameterization of the model based on empirical data. Finally, we describe the specification of illustrative policy scenarios and interpret the simulation results.

#### **3.1 Non-technical model summary**

We consider two regions (1 and 2) with four production sectors: carbon-free and tradable production  $(NC_T)$ , carbon-intensive and tradable production  $(C_T)$ , carbon-intensive and non-tradable production  $(C_NT)$ , and fossil energy production (FE). Sectors  $NC_T$ ,  $C_T$ , and  $C_NT$  correspond to the goods x, y and z, respectively, in our theoretical model of Section 2. In the numerical model, these goods can be used both as intermediate inputs into production and in final consumption. Emissions are modelled as proportional to energy use. To keep in line with the analytical model, energy can neither

<sup>&</sup>lt;sup>15</sup>  $v_m^1$ ,  $s_m^1$ ,  $\pi_m^1$  and  $\gamma_m^1$  denote the consumption tax, the output subsidy, the carbon tariff and the export rebate on good  $y_m$  in region 1, respectively.

be used in final consumption nor can it be traded between regions. Thus, we implicitly suppress the fossil-fuel channel for carbon leakage, as we want to focus on the competitiveness channel examined in the theoretical analysis.

Primary factors of production include labor, capital, and specific energy resources. Labor and capital are intersectorally mobile within a region but immobile between regions. The energy resource is specific to the energy production sector.

Producers combine primary factors and intermediate inputs at minimum cost subject to technological constraints. Production of non-energy goods is captured by three-level constant-elasticity-of-substitution (CES) cost functions describing the price-responsive demand for capital, labor, energy and other intermediate inputs. At the top level, non-energy intermediate inputs trade off with a composite of energy, capital and labor, subject to a constant elasticity of substitution. At the second level, a CES function describes the substitution possibilities between energy and a value-added composite of labor and capital. At the third level, capital and labor enter the CES value-added composite. In the production of energy, all inputs except for the specific energy resource are combined in fixed proportions. This Leontief composite trades off with the energy resource at a constant elasticity of substitution.

Final consumption demand in each region is determined by the representative agent who maximizes welfare subject to a budget constraint. Total income of the representative household consists of factor income and net revenues from emission regulation. Consumption demand of the representative agent is given as a CES composite of final consumption goods. Figures B1-B3 in Appendix B sketch the nesting of functional forms in production and consumption together with the default elasticities underlying our central case simulations.

As emissions are linked in fixed proportions to the use of energy, emission reductions in response to emission pricing will take place by energy savings. The latter can take place either through substitution of energy through other non-energy inputs or through scale reduction of production and final demand activities.

Only the two goods  $C_T$  and  $NC_T$  can be traded bilaterally (with no transport cost). A balance of payment constraint incorporates the base-year trade deficit or surplus for each region. The stylized model can reflect two alternative trade paradigms – either trade in homogeneous goods or trade in

heterogeneous goods. In case of heterogeneous goods, we follow Armington's differentiated goods approach, where domestic and foreign goods are distinguished by origin (Armington, 1969). All goods used on the domestic market in intermediate and final demand correspond to a CES composite that combines the domestically produced good and the imported good from the other region. The size of the (Armington) substitution elasticities determine how close substitutes goods produced in different regions are. In case of homogeneous trade, only net trade flows matter such that there is no crosshauling.

#### **3.2 Data and parametrization**

As to parameterization, we adopt the standard calibration procedure in applied general equilibrium analysis in which a balanced base-year dataset determines the free parameters of the functional forms (i.e., cost and expenditure functions) such that the economic flows represented in the data are consistent with the optimizing behavior of the economic agents.

To have the stylized numerical analysis closely related with our theoretical exposition, we restructure an empirical dataset in line with the fundamental settings of the theoretical part. Our dataset is based on the most recent GTAP data for the world economy (base-year 2011) with 57 sectors and 140 regions. We first map all 57 GTAP sectors to the four composite sectors in our model (see Table C1 in Appendix C). Then we construct a social accounting matrix (SAM) for the global economy based on the GTAP data. Since the  $NC_T$  good is assumed to be carbon-free, we set (fossil) energy use in this sector equal to zero.<sup>16</sup>

Next, we divide the world into two identical regions to follow the symmetry assumption in the theoretical analysis.<sup>17</sup> Thus, each entry in the SAM for region *j* is half of the corresponding entry in the global SAM. As there is no trade in the global SAM, we have to make an assumption about initial trade volumes between the two regions. For each of the two goods  $C_T$  and  $NC_T$  we simply assume that 50% of the trade observed in 2011 (according to the GTAP data) takes place between regions 1 and 2. As mentioned before, we assume no trade for  $C_NT$  and *FE*. The derived SAM for each region is displayed in Table C2 in Appendix C.

<sup>&</sup>lt;sup>16</sup> In the original GTAP dataset, this sector only accounts for 3-4% of total fossil energy use.

<sup>&</sup>lt;sup>17</sup> This implies that there are no terms-of-trade effects at the margin (before any policy is implemented).

#### **3.3 Scenarios**

Our reference scenario (*REF*) for unilateral climate policy is a situation where a single country (or country coalition) – here: region 1 – undertakes uniform emission pricing to achieve an exogenous domestic emission reduction target.<sup>18</sup> In our central case simulations, we set the unilateral emission reduction target at 20 percent of the base-year emissions. We use the stylized numerical model to quantify how the *REF* outcome changes if the region adopts in addition either full border carbon adjustment (BCA), or output-based rebating combined with a consumption tax (OBR+Tax). In both cases, the additional policies are directed only towards the C T good, i.e., the emission-intensive and trade-exposed commodity. In the BCA case, the carbon tariff and the export rebate are determined based on the domestic emission intensity (see Section 2). In the OBR+Tax case, we assume full rebating and consider different levels of the consumption tax, which is applied to both final consumption and intermediate use of the C T good. We indicate the different levels of the consumption tax as a fraction v of the OBR rate where we increase v subsequently in steps of 20 percentage points from 0% to 200%. Obviously, OBR+Tax includes output-based rebating stand-alone as a special case when we set the consumption tax to zero (v=0%). As demonstrated in our theoretical analysis (see Proposition 3 and Corollary 3), OBR+Tax is equivalent to BCA when the consumption tax is set equal (v=100%) to the implicit output subsidy under output-based rebating.

REF	Emission price only	
OBR+Tax	Output-based rebating + consumption tax for the	
	carbon-intensive and tradable good $(C_T)$	
BCA	Border carbon adjustment	

Considering that the climate is a global public good, a coherent cross-comparison of results requires that we keep global emissions constant unless we can value the damage from emissions. Here, we do not attempt to trade off the abatement cost with the benefit from avoided climate change but restrain ourselves to a cost-effectiveness analysis. Therefore, we require the abating region to adjust its unilateral emissions reduction effort such that a given global emission cap is maintained. The cap is taken as the global emission level which emerges from scenario *REF*. If additional policy measures such as OBR+Tax turn out to reduce leakage compared to *REF*, then the effective unilateral emission reduction requirement will be lower than the *REF* target.

<sup>&</sup>lt;sup>18</sup> Uniform emission pricing to achieve some emission reduction target can either be implemented through an emission tax which is set at a sufficiently high level or equivalently through an emissions cap-and-trade system.

A key parameter regarding the magnitude of emission leakage through the competitiveness channel is the Armington elasticity. The choice of the Armington elasticity determines the ease of substitution between the domestically produced good and its foreign counterpart. The higher this elasticity, the more pronounced leakage ceteris paribus becomes. To investigate the robustness of our findings, we provide simulation results for alternative choices of the Armington elasticity ranging from a lower end value of 1, via the benchmark elasticity in GTAP of 4, to an upper end value of 8. For an infinite Armington elasticity the heterogeneous goods setting transforms into the case of homogenous goods which has been the reference in our theoretical analysis. We include the case with homogenous goods in our results exposition below by referring to an infinite Armington elasticity.

#### **3.4 Results**

In our results discussion, we first check if the equivalence result between BCA and OBR+Tax holds (when v=100%). We then investigate changes in leakage rates, welfare, and production output as the key indicators of policy interest. The leakage rate is defined as the ratio of the emission change in the non-abating region over the emission reduction in the abating region. Welfare effects are defined as Hicksian equivalent variation (HEV) in income as a percentage of the pre-policy equilibrium levels – the so-called business-as-usual (BAU).

We find that the numerical results are in accordance with the equivalence results in Proposition 3 and Corollary 3. That is, given emissions pricing (tax or quotas), the combination of output-based rebating and a consumption tax equal to the OBR rate (OBR+Tax with v=100%) gives exactly the same outcome as border carbon adjustment (BCA). This equivalence result is robust independent of whether we assume homogenous or heterogeneous goods (with various Armington elasticities).

Next we turn to leakage mitigation which is a central policy justification for supplementing unilateral emission pricing with either *OBR* or *BCA*. Previous studies have suggested that *BCA* is more effective in leakage mitigation than *OBR*. Figure 1 shows how the combination of *OBR+Tax* affects leakage across alternative choices of the Armington elasticity as we increase the consumption tax from 0% to 200% of the OBR rate (note that v=0% and v=100% are replaced with respectively *OBR* and *BCA* in all the figures). As expected, leakage rates go up with higher Armington elasticities, and becomes very high with homogenous goods. Further, Figure 1 clearly shows that introducing *OBR* reduces the leakage rate significantly, and more so the higher is the Armington elasticity. The leakage rates in fact

become negative in all three cases with heterogeneous goods.<sup>19</sup> Next, we notice that the consumption tax decreases leakage further: When the consumption tax rate is set equivalent to the OBR rate (BCA) the leakage rate drops by another 2-9 percentage points compared to OBR. We also can see that leakage is further reduced when the consumption tax is increased beyond 100%.

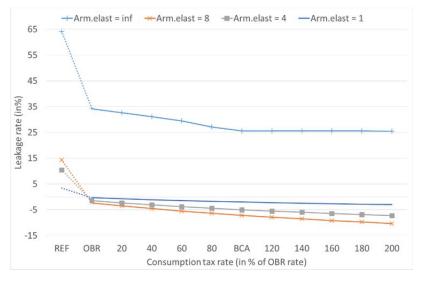

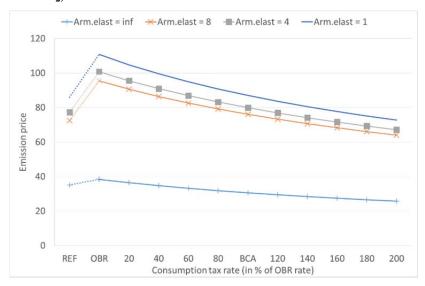

Figure 1. Leakage rates under different policy scenarios and Armington elasticities (in %)

<sup>&</sup>lt;sup>19</sup> Note that we deliberately suppress the fossil-fuel channel in our analysis, which makes leakage rates rather low to start with in the *REF* scenario (relative to most numerical analysis in the literature featuring both the fossil-fuel as well as the competitiveness channel), and explains why anti-leakage measures have a strong potential to drive leakage rates even negative. If we include the fossil fuel channel by allowing for trade in energy, none of our qualitative findings changes.

As mentioned before, a main difference between OBR and the consumption tax is that the former stimulates domestic supply while the latter dampens domestic demand. Hence, OBR will tend to increase domestic emissions, while the consumption tax has the opposite effect. Figure 2 shows the endogenous emission prices needed to reach the same global emission target (across policy scenarios for a given choice of Armington elasticity). Although OBR leads to lower leakage (as shown in Figure 1), the first order effect of higher domestic output of the  $C_T$  good dominates with respect to global emissions, implying a higher necessary emission price under OBR than under REF. If the consumption tax is introduced, however, a lower emission price is needed.

In Figure 3 we show how the policies affect economic welfare in region 1. Since we assume that global emissions are the same across all policy scenarios, we do not have to value emission changes. We first notice that the welfare effects of *OBR* are positive in the case of homogenous goods. In this case, the implicit subsidy given by *OBR* reduces the inefficient relocation of production from region 1 to region 2. On the other hand, if the substitution possibilities between domestic and foreign goods are more limited, then the distortionary negative effect of subsidising this good becomes relatively more important and dominates the former positive effect. In all the three cases with heterogeneous goods, the welfare cost for region 1 increases rather than decreases when shifting from emission pricing only (*REF*) to emission pricing combined with *OBR* (but only marginally with the Armington elasticity at a value of 8).

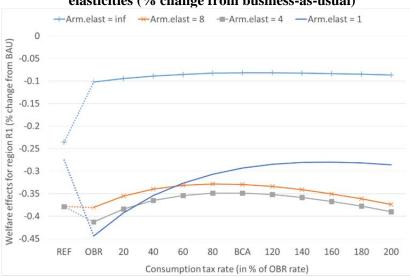

Figure 3. Welfare effects (HEV) for region 1 under different policy scenarios and Armington elasticities (% change from business-as-usual)

Figure 3 furthermore shows that it is welfare improving for region 1 to implement a consumption tax when output-based rebating is already in place, which is in line with Proposition 1 of our theoretical

analysis. This holds irrespective of the choice of Armington elasticity. The optimal consumption tax level is in the range 80-160% of the OBR-rate in the simulated cases. With homogenous goods, the benefits of the consumption tax are rather modest. With heterogeneous goods, the benefits are more pronounced, and more so the lower is the Armington elasticity. In the case with Armington elasticity equal to 1, the welfare costs are reduced by one third when *OBR* is supplemented with a consumption tax of 100% of the OBR-rate (i.e., the *BCA* case). If the consumption tax is increased to 160%, the welfare costs are approximately the same as in the *REF* case, i.e., emission pricing only.

The numerical results provide evidence that *OBR* may serve as a decent second-best policy for goods that are much exposed to foreign competition, due to high substitutability between domestic and foreign goods, but not so for goods that are less exposed. Moreover, supplementing *OBR* with a consumption tax is beneficial whether or not the good is much exposed to foreign competition. Thus, when output-based rebating is applied to a certain group of goods, the policy-relevant conclusion from our analysis is to also introduce a corresponding tax on all purchases of the same goods.

A relevant question to ask is whether the findings in Figure 3 are due to efficiency improvements, or whether it is due to terms-of-trade benefits for region 1 at the expense of region 2. Although we start from an initial *BAU* situation with no net trade in either of the tradable goods, the *REF* scenario is characterized by net export of the  $C_T$  good from region 2 to region 1 (and vice versa for the  $NC_T$  good). As both *OBR* and the consumption tax reduce the relative price of the  $C_T$  good (over the  $NC_T$  good), terms-of-trade effects for region 1 are positive as we move towards the right from *REF* in Figure 3.

In order to examine this more closely, we first consider the case where region 1 must provide a transfer to region 2 so that welfare in the latter region does not decrease vis-à-vis the *REF* case. The qualitative findings are then very similar to the ones in Figure 3, i.e., the optimal consumption tax is in the range 80-140%, and the welfare gains increase notably we lower the Armington elasticity.

Next, we consider the effects on global welfare.<sup>20</sup> According to Proposition 2, introducing such a tax should also be beneficial from a global perspective. Figure 4 shows the global welfare cost of the different policies. We notice that *OBR* increases global welfare cost across alternative values for Armington elasticities, except in the case with homogenous goods. This is similar to findings in Figure

<sup>&</sup>lt;sup>20</sup> Global welfare accounting is based on a utilitarian (Benthamite) perspective on efficiency where welfare changes of individual regions are treated as perfect substitutes.

3 for region 1. Next, we see that introducing a consumption tax in addition to *OBR* reduces global welfare cost in all four cases, which is in accordance with Proposition 2. The lowest welfare cost is obtained when the consumption tax is in the range 80-100% of the OBR rate, i.e., close to the *BCA*-equivalent rate. This holds irrespective of how close substitutes domestic and foreign goods are (including the homogenous goods case).

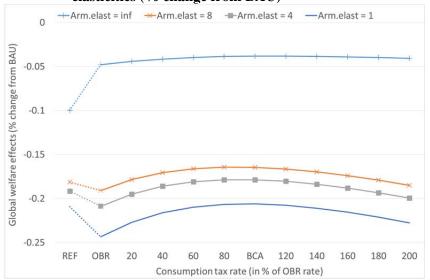

Figure 4. Global welfare effects (HEV) under different policy scenarios and Armington elasticities (% change from BAU)

Whereas the consumption tax is advantageous for region 1 and also for the two regions jointly, region 2 is mostly worse off by the consumption tax. This is due to the disadvantageous terms-of-trade effects discussed above.

Finally, we consider how the policies affect production output in the two regions. Output effects are shown in Figure 5 for the case with an Armington elasticity equal to 4. As expected, the emission price (*REF*) reduces output of the two carbon-intensive goods  $C_T$  and  $C_NT$  in region 1, and increases output of the good  $C_T$  in the other region 2. When *OBR* is introduced, the effects on output of the good  $C_T$  are turned around, as region 1 (2) marginally *increases* (*decreases*) its output compared to the *BAU* level (see the negative leakage rates in Figure 1). When the consumption tax is introduced on the good  $C_T$  in region 1, we observe that output of this good is reduced in both regions.

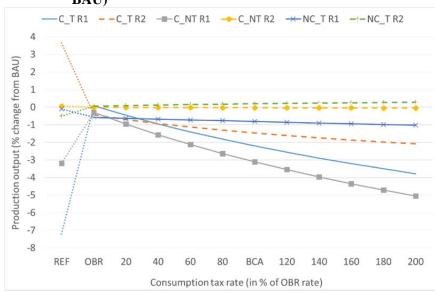

Figure 5. Production output in regions 1 and 2 under different policy scenarios (% change from BAU)

We see from Figure 5 that also the  $C_NT$  output in region 1 increases notably when OBR is implemented for the good  $C_T$ , and then decreases when the consumption tax is implemented. The explanation behind is that the two emission-intensive goods are used quite a lot as intermediate inputs into each other's production (relative to the  $NC_T$  good), see Table C2 in Appendix C. Thus, when the  $C_T$  production is stimulated by the OBR policy, this indirectly stimulates  $C_NT$  production, too (and vice versa with the consumption tax). Output of the carbon-free good  $NC_T$  in region 1 declines with the implementation of the emission price as well as with the introduction of OBR and the increase of the consumption tax from zero. This is partly due to reduced real income in region 1, and partly because production of this good uses the two carbon-intensive goods as inputs.

## 4. Concluding remarks

In the absence of world-wide cooperation to mitigate global warming, many countries consider or have introduced unilateral climate policies. This causes carbon leakage associated with the relocation of emission-intensive and trade-exposed (EITE) industries. Economic theory and numerical studies suggest that border carbon adjustment, in addition to emission pricing, can be used as a second-best instrument to improve cost-effectiveness of unilateral climate policy. However, as carbon tariffs and export rebates are politically contentious to implement, policy makers have typically chosen other instruments such as variants of output-based rebating to EITE industries.

A prime example for output-based rebating is the EU Emission Trading System (EU ETS) where emission allowances are allocated to EITE industries conditional on output. Martin et al. (2014) find that there has been substantial overallocation of allowances in the EU ETS for the given carbon leakage risk. As the optimal allocation scheme relies on data that are not publicly observable, they propose a more "feasible" allocation scheme based on easily observable characteristics of firms such as employment and historic  $CO_2$  emissions.

Our paper suggests an alternative strategy, namely to combine output-based rebating to production of EITE goods with a consumption tax on all use of the same EITE goods. We have shown analytically that it is welfare improving for a region to introduce such a consumption tax if output-based rebating is already in place. The theoretical result is confirmed when using a stylized numerical general equilibrium model calibrated to data for the world economy, highlighting that the welfare gains from such consumption taxes can be substantial. The administrative cost of adding such a consumption tax is likely to be moderate as the tax level could be set in proportion to the benchmarks already set by the emission allocation mechanisms in place. It is also important to realize that the addition of consumption taxes makes output-based rebating more robust with respect to uncertainties and political economy risks about leakage exposure: The distortive effects of allowance overallocation – by including too many sectors with limited carbon leakage risk or warranting too high rebates – are moderated.

Regarding political feasibility of anti-leakage policies, we have shown that a certain combination of output-based rebating and a consumption tax is equivalent to full border carbon adjustment as long as the carbon tariffs (and the export rebate) are not differentiated across importers. Thus, whereas border carbon adjustment may be politically contentious to introduce under current WTO rules, the same outcome can in fact be achieved by supplementing output-based rebating with a consumption tax.

We thus conclude that supplementing output-based rebating with a consumption tax constitutes smart hedging against carbon leakage: Compared to output-based rebating stand-alone it constitutes a robust strategy for improving cost-effectiveness of unilateral climate policy; compared to border carbon adjustment it limits the risks of potentially detrimental trade disputes.

## **Appendix A: Proofs and derivations**

#### Proof of Lemma 1:

Differentiating welfare (5) with respect to the consumption tax we get:

(11)  
$$\frac{\partial W^{1}}{\partial v^{1}} = u_{x}^{1}\left(\cdot\right)\frac{\partial \tilde{x}^{1}}{\partial v^{1}} + u_{y}^{1}\left(\cdot\right)\frac{\partial \tilde{y}^{1}}{\partial v^{1}} + u_{z}^{1}\left(\cdot\right)\frac{\partial \tilde{z}^{1}}{\partial v^{1}} - c_{x}^{x1}\left(\cdot\right)\frac{\partial x^{1}}{\partial v^{1}} - c_{y}^{y1}\left(\cdot\right)\frac{\partial y^{1}}{\partial v^{1}} - c_{z}^{z1}\left(\cdot\right)\frac{\partial z^{1}}{\partial v^{1}} - \left(c_{e}^{y1}\left(\cdot\right) + \tau\right)\frac{\partial e^{z1}}{\partial v^{1}} - \tau\left(\frac{\partial e^{y2}}{\partial v^{1}} + \frac{\partial e^{z2}}{\partial v^{1}}\right)$$

By using the first-order conditions (2) and (3) we can simplify this equation:

$$\frac{\partial W^{1}}{\partial v^{1}} = p^{x} \left( \frac{\partial \tilde{x}^{1}}{\partial v^{1}} - \frac{\partial x^{1}}{\partial v^{1}} \right) + \left( p^{y} + v^{1} \right) \frac{\partial \tilde{y}^{1}}{\partial v^{1}} - \left( p^{y} + s^{1} \right) \frac{\partial y^{1}}{\partial v^{1}} + p^{z} \left( \frac{\partial \tilde{z}^{1}}{\partial v^{1}} - \frac{\partial z^{1}}{\partial v^{1}} \right) - \left( \tau - t^{1} \right) \frac{\partial e^{z^{1}}}{\partial v^{1}} - \tau \left( \frac{\partial e^{y^{2}}}{\partial v^{1}} + \frac{\partial e^{z^{2}}}{\partial v^{1}} \right)$$

In addition, from (4), we must have:

(12) 
$$\frac{\partial p^{y}}{\partial v^{l}} \left( y^{l} - \tilde{y}^{l} \right) + p^{y} \left( \frac{\partial y^{l}}{\partial v^{l}} - \frac{\partial \tilde{y}^{l}}{\partial v^{l}} \right) + \frac{\partial p^{x}}{\partial v^{l}} \left( x^{l} - \tilde{x}^{l} \right) + p^{x} \left( \frac{\partial x^{l}}{\partial v^{l}} - \frac{\partial \tilde{x}^{l}}{\partial v^{l}} \right) = 0 \quad ; \quad \frac{\partial z^{l}}{\partial v^{l}} = \frac{\partial \tilde{z}^{l}}{\partial v^{l}}$$

We assume that the emission tax is set equal to the Pigouvian tax, i.e.,  $t^1 = \tau$ . Using equation (12) we can then further simplify equation (11):

$$\frac{\partial W^{1}}{\partial v^{1}} = p^{v} \left( \frac{\partial y^{1}}{\partial v^{1}} - \frac{\partial \tilde{y}^{1}}{\partial v^{1}} \right) + \frac{\partial p^{v}}{\partial v^{1}} \left( y^{1} - \tilde{y}^{1} \right) + \frac{\partial p^{x}}{\partial v^{1}} \left( x^{1} - \tilde{x}^{1} \right) + \left( p^{v} + v^{1} \right) \frac{\partial \tilde{y}^{1}}{\partial v^{1}} - \left( p^{v} + s^{1} \right) \frac{\partial y^{1}}{\partial v^{1}} - \tau \left( \frac{\partial e^{v^{2}}}{\partial v^{1}} + \frac{\partial e^{z^{2}}}{\partial z^{2}} \frac{\partial z^{2}}{\partial v^{1}} \right) \\ = v^{1} \frac{\partial \tilde{y}^{1}}{\partial v^{1}} - s^{1} \frac{\partial y^{1}}{\partial v^{1}} - \tau \left( \frac{\partial e^{v^{2}}}{\partial y^{2}} \frac{\partial y^{2}}{\partial v^{1}} + \frac{\partial e^{z^{2}}}{\partial z^{2}} \frac{\partial z^{2}}{\partial v^{1}} \right) + \frac{\partial p^{v}}{\partial v^{1}} \left( y^{1} - \tilde{y}^{1} \right) + \frac{\partial p^{x}}{\partial v^{1}} \left( x^{1} - \tilde{x}^{1} \right)$$

where we also used the fact that emissions in region 2 are only affected via production changes of good y and z in region 2. For a given  $s^1$  (from the OBR regulation), we can solve for the optimal  $v^1$  by setting  $\partial W^1 / \partial v^1 = 0$ . This gives equation (6).

#### Sign of first factor in equation (6):

To see that the first factor of (6) is negative, note that equations (2) and (3) imply  $u_y^1 - c_y^{y_1} = v^1 - s^1$ . Because the second order derivatives are non-zero and finite, an increase in  $v^1$  entails that  $u_y^1$ increases and  $c_y^{y_1}$  decreases when  $s^1$  is constant. This implies  $\partial \tilde{y}^1 / \partial v^1 < 0$  and  $\partial y^1 / \partial v^1 < 0$ , because  $u_{yy}^1 < 0$  and  $c_{yy}^1 > 0$ .

#### Derivation of equation (9):

We differentiate equation (8) and follow the steps explained in the proof of Lemma 1. This gives:

$$\begin{split} \frac{\partial W^{G}}{\partial v^{1}} &= \sum_{j=1,2} \left[ u_{x}^{j} \frac{\partial \tilde{x}^{j}}{\partial v^{1}} + u_{y}^{j} \frac{\partial \tilde{y}^{j}}{\partial v^{1}} + u_{z}^{j} \frac{\partial \tilde{z}^{j}}{\partial v^{1}} - c_{x}^{yj} \frac{\partial x^{j}}{\partial v^{1}} - c_{z}^{zj} \frac{\partial z^{j}}{\partial v^{1}} - \left(c_{e}^{yj} + \tau\right) \frac{\partial e^{yj}}{\partial v^{1}} - \left(c_{e}^{zj} + \tau\right) \frac{\partial e^{zj}}{\partial v^{1}} \right] \\ &= \sum_{j=1,2} \left[ p^{x} \left( \frac{\partial \tilde{x}^{j}}{\partial v^{1}} - \frac{\partial x^{j}}{\partial v^{1}} \right) + \left( p^{y} + v^{j} \right) \frac{\partial \tilde{y}^{j}}{\partial v^{1}} - \left( p^{y} + s^{j} \right) \frac{\partial y^{j}}{\partial v^{1}} \right] - \left( \tau - t^{1} \right) \frac{\partial e^{y1}}{\partial v^{1}} - \left( \tau - t^{1} \right) \frac{\partial e^{y2}}{\partial v^{1}} - \tau \left( \frac{\partial e^{y2}}{\partial v^{1}} + \frac{\partial e^{z2}}{\partial v^{1}} \right) \\ &= \sum_{j=1,2} \left[ p^{y} \left( \frac{\partial y^{j}}{\partial v^{1}} - \frac{\partial \tilde{y}^{j}}{\partial v^{1}} \right) + \frac{\partial p^{y}}{\partial v^{1}} \left( y^{j} - \tilde{y}^{j} \right) + \frac{\partial p^{x}}{\partial v^{1}} \left( x^{j} - \tilde{x}^{j} \right) + \left( p^{y} + v^{j} \right) \frac{\partial \tilde{y}^{j}}{\partial v^{1}} - \left( p^{y} + s^{j} \right) \frac{\partial y^{j}}{\partial v^{1}} \right] - \tau \left( \frac{\partial e^{y2}}{\partial v^{1}} + \frac{\partial e^{z2}}{\partial v^{1}} \right) \\ &= \sum_{j=1,2} \left[ v^{j} \frac{\partial \tilde{y}^{j}}{\partial v^{1}} - s^{j} \frac{\partial y^{j}}{\partial v^{1}} + \frac{\partial p^{y}}{\partial v^{1}} \left( y^{j} - \tilde{y}^{j} \right) + \frac{\partial p^{x}}{\partial v^{1}} \left( x^{j} - \tilde{x}^{j} \right) \right] - \tau \left( \frac{\partial e^{y2}}{\partial v^{1}} + \frac{\partial e^{z2}}{\partial v^{1}} \right) \\ &= \sum_{j=1,2} \left[ v^{j} \frac{\partial \tilde{y}^{j}}{\partial v^{1}} - s^{j} \frac{\partial y^{j}}{\partial v^{1}} \right] - \tau \left( \frac{\partial e^{y2}}{\partial v^{1}} + \frac{\partial e^{z2}}{\partial v^{1}} \right) \\ &= v^{1} \frac{\partial \tilde{y}^{j}}{\partial v^{1}} - s^{1} \frac{\partial y^{j}}{\partial v^{1}} - \tau \left( \frac{\partial e^{y2}}{\partial v^{2}} + \frac{\partial e^{z2}}{\partial v^{2}} \right) \\ &= v^{1} \frac{\partial \tilde{y}^{j}}{\partial v^{1}} - s^{1} \frac{\partial y^{j}}{\partial v^{1}} - \tau \left( \frac{\partial e^{y2}}{\partial v^{2}} + \frac{\partial e^{z2}}{\partial z^{2}} \right) \\ &= v^{1} \frac{\partial \tilde{y}^{j}}{\partial v^{1}} - s^{1} \frac{\partial y^{j}}{\partial v^{1}} - \tau \left( \frac{\partial e^{z2}}{\partial v^{2}} + \frac{\partial e^{z2}}{\partial z^{2}} \right) \\ &= v^{1} \frac{\partial \tilde{y}^{j}}{\partial v^{1}} - s^{1} \frac{\partial y^{j}}{\partial v^{1}} - \tau \left( \frac{\partial e^{z2}}{\partial v^{2}} + \frac{\partial e^{z2}}{\partial z^{2}} \right) \\ &= v^{1} \frac{\partial \tilde{y}^{j}}{\partial v^{1}} - s^{1} \frac{\partial v^{j}}{\partial v^{1}} - \frac{\partial e^{z2}}{\partial v^{2}} + \frac{\partial e^{z2}}{\partial z^{2}} \right) \\ &= v^{1} \frac{\partial v^{j}}{\partial v^{1}} - v^{1} \frac{\partial e^{z}}{\partial v^{2}} - v^{1} + \frac{\partial e^{z2}}{\partial z^{2}} \frac{\partial v^{j}}{\partial v^{1}} + \frac{\partial e^{z2}}{\partial z^{2}} \right) \\ &= v^{1} \frac{\partial v^{j}}{\partial v^{j}} - v^{1} \frac{\partial v^{j}}{\partial v^{j}} + \frac{\partial e^{z2}}{\partial v^{2$$

We also used  $c_e^{y^2} = c_e^{z^2} = t^2 = s^2 = 0$ . Setting  $\partial W^G / v^{1,G} = 0$  gives equation (9).

#### Proof of Corollary 3:

We now extend the model to several heterogeneous *EITE* goods  $y_{m}$ , with  $m = \{1, 2, ..., M\}$ . The  $y_m$ goods produced in different regions are imperfect substitutes. The representative consumer's utility from consumption in region *j* is given by  $u^j \left(\tilde{x}^j, \tilde{y}_1^{j1}, \tilde{y}_2^{j1}, ..., \tilde{y}_{M}^{j1}, \tilde{y}_1^{j2}, \tilde{y}_2^{j2}, ..., \tilde{y}_{M}^{j2}, \tilde{z}^j\right)$ . We assume that the Hessian matrix associated with the consumers' utility maximization problem is negative definite and that  $u_{x^j}^j \equiv \partial u^j / \partial x^j, u_{y_m^{j1}}^{j1}, u_{y_m^{j2}}^{j2}, u_{z^j}^{j2} > 0$  for all  $m \in M$ . The market equilibrium conditions and the first-order conditions w.r.t. goods *x* and *z* are not affected by the extension to several heterogeneous y goods (i.e., they remain as in equations (1), (2), (3) and (10)). We therefore omit good x and z from the analysis below (except in budget constraints).

Let  $y_m^{ij}$  ( $\tilde{y}_m^{ij}$ ) denote good  $y_m$  produced in region *j* and sold (consumed) in region *i*. The market equilibrium condition for each  $y_m$  good is:

(13) 
$$y_m^{ij} = \widetilde{y}_m^{ij} \quad i, j \in \{1, 2\}, \forall m \in M,$$

and we have  $y_m^j = y_m^{1j} + y_m^{2j}$ . We now show that the first-order conditions w.r.t.  $y_m^j$  are equal across the regimes. The profit maximization problem for the producer of  $y_m^j$  under OBR is:

$$\max_{y_m^{1j}, y_m^{2j}, e^{y_m j}} \left[ \left( p^{y_m 1j} + s_m^j \right) y_m^{1j} + \left( p^{y_m 2j} + s_m^j \right) y_m^{2j} - c^{y_m j} (y_m^j, e^{y_m j}) - t^j e^{y_m j} \right].$$

for all  $m \in M$ . Here  $p^{y_m ij}$  refers to the price of good  $y_m$  sold in region *i* and produced in region *j*. Further,  $s_m^j$ ,  $e^{y_m j}$  and  $c^{y_m j}(\cdot)$  refer to the output subsidy, emissions, and production costs related to  $y_m$ , respectively.

The associated first-order conditions imply:

(14)  
$$p^{y_m 11} + s_m^1 = p^{y_m 21} + s_m^1 = c_y^{y_m 1}$$
$$p^{y_m 12} = p^{y_m 22} = c_y^{y_m 2}$$
$$-c_e^{y_m 1} = t^1 \quad ; \quad c_e^{y_m 2} = 0$$

for all  $m \in M$ . In the BCA case, competitive producers of y in region j maximize profits:

$$\max_{y_m^{1j}, y_m^{2j}, e^{y_m j}} \left[ \left( p^{y_m 1j} - \pi_m^i \right) y_m^{1j} + \left( p^{y_m 2j} + \gamma_m^j \right) y_m^{2j} - c^{y_m j} (y_m^j, e^{y_m j}) - t^j e^{y_m j} \right] \quad i, j \in \{1, 2\} (i \neq j), \forall m \in M$$

Here  $\pi_m^i$  and  $\gamma_m^j$  denote the carbon tariff and export rebate on good  $y_m$  in region *j*, respectively. This gives the following first-order conditions for interior solution:

(15)  
$$p^{y_m 11} = p^{y_m 21} + \gamma_m^1 = c_y^{y_m 1}$$
$$p^{y_m 12} - \pi_m^1 = p^{y_m 22} = c_y^{y_m 2}$$
$$-c_e^{y_m 1} = t^1 \quad ; \quad -c_e^{y_m 2} = 0$$

for all  $m \in M$ . Finally, the representative consumer in region *j* maximizes welfare:

$$\max_{\omega} \left[ u^{j}(\omega) - \left( p^{xj} \widetilde{x}^{j} + \left[ \sum_{m \in M} \left( \left( p^{y_{m}j_{1}} + v_{m}^{j} \right) \widetilde{y}_{m}^{j_{1}} + \left( p^{y_{m}j_{2}} + v_{m}^{j} \right) \widetilde{y}_{m}^{j_{2}} \right) \right] + p^{zj} \widetilde{z}^{j} \right) \right]$$

where  $\omega = \tilde{x}^{j}, \tilde{y}_{1}^{j1}, \tilde{y}_{2}^{j1}, ..., \tilde{y}_{M}^{j1}, \tilde{y}_{1}^{j2}, \tilde{y}_{2}^{j2}, ..., \tilde{y}_{M}^{j2}, \tilde{z}^{j}$ . The associated first-order conditions for the *y* goods are:

(16) 
$$u_{y_m^{j_i}}^j = p^{y_m j i} + v_m^j \quad i = \{1, 2\}, \forall m \in M,$$

which is valid under OBR and BCA ( $v^1 = 0$  under BCA).

The budget constraint required for import expenditures to equal export revenue in region *j* is:

(17) 
$$\sum_{m \in M} \left( p^{y_{m}jj} y_{m}^{jj} - p^{y_{m}ji} \widetilde{y}_{m}^{ji} \right) + p^{x} \left( x^{j} - \widetilde{x}^{j} \right) = 0 \quad i, j \in \{1, 2\} \left( i \neq j \right),$$

under OBR and BCA.

Following the steps in the derivation of equation (6), we find the optimal consumer tax with M heterogeneous y goods:

$$v_m^{1**} = \left(\frac{\partial \tilde{y}_m^{11}}{\partial v_m^1} + \frac{\partial \tilde{y}_m^{12}}{\partial v_m^1}\right)^{-1} \left(\sum_{m \in \mathcal{M}} \left[s_m^1 \frac{\partial y_m^1}{\partial v_m^1} + \tau \left(\frac{\partial e^{y_m 2}}{\partial y_m^2} \frac{\partial y_m^2}{\partial v_m^1}\right) - \frac{\partial p^{y_m 21}}{\partial v_m^1} y_m^{21} + \frac{\partial p^{y_m 12}}{\partial v_m^1} \tilde{y}_m^{12}\right] + \tau \frac{\partial e^{z^2}}{\partial z^2} \frac{\partial z^2}{\partial v^1} + \frac{\partial p^x}{\partial v_m^1} \left(\tilde{x}^1 - x^1\right)\right)$$

The interpretation is similar to that of equation (6), with condition (7) replaced with:

$$\sum_{m \in M} \left( \frac{\partial e^{y_m 2}}{\partial y_m^2} \frac{\partial y_m^2}{\partial v_m^1} \right) + \frac{\partial e^{z^2}}{\partial z^2} \frac{\partial z^2}{\partial v^1} < 0$$

The first part of Corollary 3 follows.

We now turn to the second part of Corollary 3. Table A1 summarizes and compares the first-order conditions for the y goods:

	OBR + tax	BCA
Production $y_m^1$	$p^{y_m 11} + s_m^1 = p^{y_m 21} + s_m^1 = c_y^{y_m 1}$	$p^{y_m^{11}} = p^{y_m^{21}} + \gamma_m^1 = c_y^{y_m^{11}}$
Production $y_m^2$	$p^{v_m 12} = p^{v_m 22} = c_y^{v_m 2}$	$p^{v_m^{12}} - \pi_m^1 = p^{v_m^{22}} = c_y^{v_m^{22}}$
Abatement	$-c_e^{y_m 1} = t^1$ ; $c_e^{y_m 2} = 0$	$-c_e^{y_m 1} = t^1$ ; $c_e^{y_m 2} = 0$
Consumption $\tilde{y}_m^{11}$	$u_{y_m^{11}} = p^{y_m^{11}} + v_m^1 = p^{y_m^{21}} + v_m^1$	$u_{y_m^{11}} = p^{y_m^{11}} = p^{y_m^{21}} + \gamma_m^1$
Consumption $\tilde{y}_m^{12}$	$u_{y_m^{12}} = p^{y_m^{12}} + v_m^1 = p^{y_m^{22}} + v_m^1$	$u_{y_m^{12}} = p^{y_m^{12}} = p^{y_m^{22}} + \pi_m^1$

Table A1. First-order conditions under the two regimes with *M* heterogeneous y goods.

Note that equal consumption across regimes in region 1 implies equal consumption in region 2, given equal production levels and the market equilibrium condition (13). Table A1 shows that the first-order conditions are equal across the regimes if  $v_m^1 = s_m^1 = \gamma_m^1 = \pi_m^1$ . This proves the last part of Corollary 3.

### Appendix B: Algebraic summary of the numerical CGE model

Our stylized multi-sector multi-region computable general equilibrium model is formulated as a system of nonlinear inequalities. The inequalities correspond to the two classes of conditions associated with a general equilibrium: (i) exhaustion of product (zero profit) conditions for producers with constant returns to scale; and (ii) market clearance for all goods and factors. The former class determines activity levels, and the latter determines price levels. In equilibrium, each variable is linked to one inequality condition: an activity level to an exhaustion of product constraint and a commodity price to a market clearance condition. In our algebraic exposition, the notation is  $\Pi_{gr}^{z}$  used to denote the unit profit function (calculated as the difference between unit revenue and unit cost) for production with constant returns to scale of sector *g* in region *r*, where *z* is the name assigned to the associated production activity. Differentiating the unit profit function with respect to input and output prices provides compensated demand and supply coefficients (Hotelling's lemma), which appear subsequently in the market clearance conditions. We use *g* as an index for all sectors/commodities except primary fossil energy and index *r* (aliased with *s*) to denote region. Furthermore, we indicate complementarity between equilibrium conditions and variables with the operator  $\perp$ .

Tables B1–B6 explain the notations for variables and parameters employed within our algebraic exposition. Figures B1-B3 sketch the nesting of functional forms in production and consumption together with the default elasticities underlying our central case simulations. Numerically, the model is implemented in GAMS (Brooke et al., 1996)<sup>21</sup> and solved using PATH (Dirkse and Ferris, 1995).<sup>22</sup>

Table D.1. multes and sets				
G	Set of all commodities { <i>NC_T</i> , <i>C_T</i> , <i>C_NT</i> , <i>FE</i> }			
EG	Subset of primary energy goods { <i>FE</i> }			
R	Set of regions {1, 2}			
g (alias i)	Index for sectors and commodities			
r (alias s)	Index for regions			

Table B.1. Indices and sets

#### Table B.2. Activity variables

$Y_{gr}$	Production of commodity $g$ in region $r$
$M_{gr}$	Material composite for commodity $g$ in region $r$
$K\!L_{gr}$	Value-added composite for commodity $g$ in region $r$
$A_{g'}$	Armington aggregate of commodity $g$ in region $r$
$I\!M_{gr}$	Import aggregate of commodity $g$ in region $r$
$C_r$	Consumption composite in region $r$

## Table B.3. Price variables

$p_{gr}$	Price of commodity $g$ in region $r$
$p_{gr}^{M}$	Price of material composite for commodity $g$ in region $r$
$p_{\scriptscriptstyle gr}^{\scriptscriptstyle K\!L}$	Price of value-added composite for commodity $g$ in region $r$
$p^{A}_{g'}$	Price of Armington aggregate of commodity $g$ in region $r$
$p_{\scriptscriptstyle gr}^{\scriptscriptstyle M}$	Price of aggregate imports of commodity $g$ in region $r$
$p_r^C$	Price of consumption composite in region r
W <sub>r</sub>	Price of labor (wage rate) in region <i>r</i>
V <sub>r</sub>	Price of capital services (rental rate) in region $r$
$q_{r}$	Rent for primary energy resource in region r
$p_r^{CO2}$	Price of carbon emissions in region r

#### Table B.4. Cost shares

$ heta_{g^r}^M$	Cost share of material composite in production of commodity $g$ in region $r$
$ heta_{gr}^{\scriptscriptstyle FE}$	Cost share of primary energy in capital-labor-energy composite input to production of
	commodity $g$ in region $r$
$ heta_{igr}^{M\!N}$	Cost share of input $i$ in material composite of commodity $g$ in region $r$
$ heta_{g^r}^{\!$	Cost share of capital within the value-added of commodity $g$ in region $r$
$ heta_r^{\mathcal{Q}}$	Cost share of primary energy resource in primary energy production in region $r$
$ heta_{F\!E,r}^{L\!N}$	Cost share of labor in non-resource composite of primary energy production in region $r$
$ heta_{F\!E,r}^{\!$	Cost share of capital in non-resource input to primary energy production in region $r$
$ heta_{g,FE,r}^{\!\scriptscriptstyle N}$	Cost share of good $g$ in non-resource input to primary energy production in region $r$
$ heta_{g^{\star}}^4$	Cost share of domestic input $g$ in the Armington composite of commodity $g$ in region $r$
$ heta_{gsr}^{IM}$	Cost share of commodity $g$ from region $s$ in import composite of region $r$
$ heta_{gr}^{C}$	Cost share of commodity $g$ in consumption composite of region $r$

# Table B.5. Elasticities of substitution

$\sigma_{gr}^{KLEM}$	Substitution between the material composite and the energy-value-added aggregate in
8	production of commodity $g$ in region $r$
$\sigma_{\!\!gr}^{\!\scriptscriptstyle K\!L\!E}$	Substitution between primary fossil energy and the value-added nest in production of
8	commodity $g$ in region $r$
$\sigma^{\scriptscriptstyle M}_{\scriptscriptstyle gr}$	Substitution between material inputs within the material composite in production of
gr	commodity $g$ in region $r$
$\sigma_{\scriptscriptstyle gr}^{\scriptscriptstyle K\!\scriptscriptstyle L}$	Substitution between the capital and labor within the value-added composite in
gr	production of commodity $g$ in region $r$
$\sigma^{\!$	Substitution between natural resource input and the composite of other inputs in primary
g	energy production in region r
$\sigma^{\!\scriptscriptstyle A}_{\!\scriptscriptstyle gr}$	Substitution between import composite and domestic input to Armington production of
g	commodity $g$ in region $r$
$\sigma^{\scriptscriptstyle I\!M}_{\scriptscriptstyle gr}$	Substitution between imports from different regions within the import composite of
gr	commodity $g$ in region $r$
$\sigma_r^{\scriptscriptstyle C}$	Substitution between commodity inputs to composite consumption in region $r$

#### Table B.6. Endowments

Aggregate labor endowment in region <i>r</i>
Capital endowment in region r
Resource endowment of primary fossil energy in region $r$
Endowment with $CO_2$ emission allowances in region $r$
$CO_2$ emissions coefficient for primary fossil energy in region $r$

### Zero profit conditions

• Production of goods except fossil primary energy (  $g \notin EG$  ):

$$\begin{split} \Pi_{gr}^{v} &= p_{gr} - \left[ \theta_{gr}^{M} p_{gr}^{M \left(1 - \sigma_{gr}^{KLEM}\right)} + \left(1 - \theta_{gr}^{M}\right) \right] \left[ \theta_{gr}^{FE} \left( p_{FE,r} + a_{FE,r}^{CO_2} p_r^{CO_2} \right)^{\left(1 - \sigma_{gr}^{KLE}\right)} \\ &+ \left(1 - \theta_{gr}^{FE}\right) p_{gr}^{KL \left(1 - \sigma_{gr}^{KLE}\right)} \right]^{\left(1 - \sigma_{gr}^{KLEM}\right)} \\ \end{bmatrix}^{\left(1 - \sigma_{gr}^{KLEM}\right)} \\ &= 0 \qquad \bot \quad Y_{gr} \end{split}$$

• Sector-specific material composite ( $g \notin EG$ ):

$$\Pi_{gr}^{M} = p_{gr}^{M} - \left[\sum_{i \notin EG} \theta_{igr}^{MN} p_{ir}^{\mathcal{A}\left(1 - \sigma_{gr}^{M}\right)}\right]^{\frac{1}{\left(1 - \sigma_{gr}^{M}\right)}} \leq 0 \qquad \bot \quad M_{gr}$$

• Sector-specific value-added aggregate ( $g \notin EG$ ):

$$\Pi_{gr}^{KL} = p_{gr}^{KL} - \left[ \theta_{gr}^{K} v_{r}^{\left(1 - \sigma_{gr}^{KL}\right)} + \left(1 - \theta_{gr}^{K}\right) w_{r}^{\left(1 - \sigma_{gr}^{KL}\right)} \right]^{\frac{1}{\left(1 - \sigma_{gr}^{KL}\right)}} \leq 0 \qquad \bot \quad KL_{gr}^{KL} = 0$$

• Production of primary fossil fuel:

$$\Pi_{FE,r}^{Y} = p_{FE,r} - \left[\theta_{r}^{Q}q_{r}^{\left(1-\sigma_{r}^{Q}\right)} + \left(1-\theta_{r}^{Q}\right)\left[\theta_{FE,r}^{LN}w_{r} + \theta_{FE,r}^{KN}v_{r} + \sum_{g \notin EG}\theta_{g,FE,r}^{N}p_{gr}^{A}\right]^{\left(1-\sigma_{r}^{Q}\right)}\right]^{\frac{1}{\left(1-\sigma_{r}^{Q}\right)}} \leq 0 \qquad \bot \quad Y_{FE,r}^{N}$$

• Armington aggregate ( $g \notin EG$ ):

$$\Pi_{gr}^{A} = p_{gr}^{A} - \left[\theta_{gr}^{A} p_{gr}^{\left(1-\sigma_{gr}^{A}\right)} + \left(1-\theta_{gr}^{A}\right) p_{gr}^{IM\left(1-\sigma_{gr}^{A}\right)}\right]^{\frac{1}{\left(1-\sigma_{gr}^{A}\right)}} \le 0 \qquad \bot \quad A_{gr}$$

• Import composite ( $g \notin EG$ ):

$$\Pi_{gr}^{IM} = p_{gr}^{IM} - \left[\sum_{s \neq r} \theta_{gsr}^{IM} p_{gs}^{\left(1 - \sigma_{gr}^{IM}\right)}\right]^{\frac{1}{\left(1 - \sigma_{gr}^{IM}\right)}} \le 0 \qquad \bot \quad IM_{gr}$$

• Consumption composite:

$$\Pi_r^C = p_r^C - \left[\sum_{g \notin EG} \theta_{gr}^C p_{gr}^{A\left(1 - \sigma_{gr}^C\right)}\right]^{\frac{1}{\left(1 - \sigma_{gr}^C\right)}} \le 0 \qquad \bot \quad C_r$$

### Market clearance conditions

• Labor:

$$\overline{L}_{r} \geq Y_{FE,r} \frac{\partial \Pi_{FE,r}^{Y}}{\partial w_{r}} + \sum_{g \notin EG} KL_{gr} \frac{\partial \Pi_{gr}^{KL}}{\partial w_{r}} \qquad \bot \quad w_{r}$$

• Capital:

$$\overline{K}_{r} \geq Y_{FE,r} \frac{\partial \Pi_{FE,r}^{Y}}{\partial v_{r}} + \sum_{g \notin EG} KL_{gr} \frac{\partial \Pi_{gr}^{KL}}{\partial v_{r}} \qquad \bot \quad v_{r}$$

• Primary fossil energy resource:

$$\overline{Q}_r \ge Y_{FE,r}^{Y} \frac{\partial \Pi_{FE,r}^{Y}}{\partial q_r} \qquad \bot \quad q_r$$

• Material composite ( $g \notin EG$ ):

$$M_{gr} \ge Y_{gr} \frac{\partial \Pi_{gr}^{Y}}{\partial p_{gr}^{M}} \qquad \bot \quad p_{gr}^{M}$$

• Value-added ( $g \notin EG$ ):

$$KL_{gr} \geq Y_{gr} \frac{\partial \Pi_{gr}^{Y}}{\partial p_{gr}^{KL}} \qquad \bot \quad p_{gr}^{KL}$$

• Armington aggregate ( $g \notin EG$ ):

$$A_{gr} \ge C_r \frac{\partial \Pi_r^C}{\partial p_{gr}^A} + Y_{FE,r} \frac{\partial \Pi_{FE,r}^Y}{\partial p_{gr}^A} + \sum_{i \notin EG} M_{ir} \frac{\partial \Pi_{ir}^M}{\partial p_{gr}^A} \qquad \bot \quad p_{gr}^A$$

• Import composite ( $g \notin EG$ ):

$$IM_{gr} \ge A_{gr} \frac{\partial \prod_{gr}^{A}}{\partial p_{gr}^{IM}} \qquad \bot \quad p_{gr}^{IM}$$

• Goods except primary energy ( $g \notin EG$ ):

$$Y_{gr} \ge A_{gr} \frac{\partial \Pi_{gr}^{A}}{\partial p_{gr}} + \sum_{s \neq r} IM_{gs} \frac{\partial \Pi_{gs}^{IM}}{\partial p_{gs}} \qquad \bot \quad p_{gr}$$

• Primary energy:

$$Y_{FE,r} \ge \sum_{g \notin EG} Y_{gr} \frac{\partial \Pi_{gr}^{Y}}{\partial \left( p_{FE,r} + a_{FE,r}^{CO_2} p_r^{CO_2} \right)} \qquad \bot \quad p_{FE,r}$$

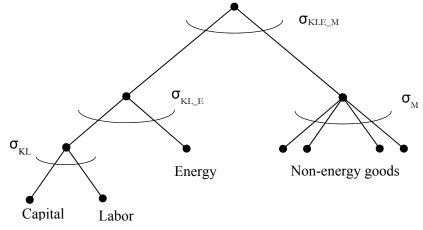

• Private consumption (*g* = *C*):

$$p_r^C C_r \ge w_r \overline{L}_r + v_r \overline{K}_r + q_r \overline{Q}_r + p_r^{CO_2} \overline{CO2}_r \qquad \perp \ p_r^C$$

• Carbon emissions:

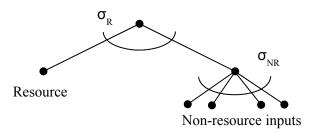

$$\overline{CO2}_r \ge a_{FE,r}^{CO_2} Y_{FE,r} \quad \bot \quad p_r^{CO_2}$$

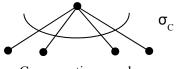

Elasticities:  $\sigma_{KLE\_M} = 0.25$ ;  $\sigma_{KLE} = 0.5$ ;  $\sigma_M = 0$ ;  $\sigma_{KL} = 1$ 

Elasticities:  $\sigma_R = 0.9$ ;  $\sigma_{NR} = 0$ 

Consumption goods

Elasticities:  $\sigma_C$  =0.5

# Appendix C: Mapping of GTAP sectors and base-year data

Table C1 shows the mapping of the 57 GTAP sectors to the four composite sectors in our model.

Model sectors	GTAP sectors
FE: fossil energy composite	Coal; Crude oil; Gas (extraction and distribution)
C_T: carbon-intensive and tradable goods	Refined oil; Ferrous metals; Non-ferrous metals;
	Non-metallic minerals; Chemical rubber products;
	Other machinery and equipment; Paper and paper
	products
C_NT: carbon-intensive and non-tradable goods	Electricity; All transport sectors (air, water, rail, road)
NC_T: carbon-free and tradable goods	All remaining goods and services

Table C1. Mapping of GTAP sectors to composite model sectors

Table C2 shows the derived SAM for each region. The entries constitute value flows with negative values being inputs (demands) and positive values being output or endowments (supplies). Since the base-year data is given in value terms, we have to choose units for goods and factors to separate price and quantity observations. A commonly used convenient convention is to choose units for both goods and factors to have a price of unity in the base-year such that values readily transfer into quantities.<sup>23</sup> In general, data consistency of a social accounting matrix requires that the sums of each of the rows and columns equal zero. Whereas market equilibrium conditions (including trade balance) are associated with the rows, the columns capture the zero-profit condition for production sectors as well as the income balance for the aggregate household sector.
