# A CRIMINOMETRIC STUDY USING PANEL DATA AND LATENT VARIABLES ${ }^{1}$ 

by<br>Jørgen Aasness* Erling Eide** and Terje Skjerpen*

#### Abstract

A behavioural model of crime is developed and applied on panel data on the number of crimes and clear-ups for the 53 police districts in Norway for the period 1970-78. The model consists of behavioural relations of the criminals and the police, and of measurement relations allowing for random and systematic errors in the registered crimes and clear-ups. The identification of the model, and the implied testable hypotheses on the covariance structure of the crimes and clearups, depend crucially on the specification of how the distribution of the police district effects of the criminal behaviour and of the police behaviour change over time. The effect of the latent clear-up probability on the crime rate is found to be significantly negative. In our preferred model, a one percent increase in the clearup probability reduces the number of crimes by about one percent. LISREL 7 is applied.

Key words: economics of crime, deterrence, panel data, latent variables, measurement errors.

## 1. INTRODUCTION

Virtually all criminal legislation is pervaded by the belief that punishment has a deterrent effect on crime. This belief was strengthened by a study of Becker (1968) where, in an economic model of crime, it was assumed that crime is a risky business and that people act as rational utility maximizers. When a person considers all benefits and costs of a possible crime, the expected utility of the crime will be reduced when either the probability of being caught and punished or the severity of punishment is increased. Not surprisingly, a reduction in the expected utility of crime will lead to a reduction in the number of crimes.

In the last 20 years the hypothesis of a deterrent effect of punishment has been confirmed by several empirical studies of total crime and of various types of crime, but not by all of them. (See reviews in Blumstein, Cohen and Nagin (1978), Heineke (1978), Bleyleveld (1980), Schmidt and Witte (1984), and Cameron (1988)). Furthermore, methodological problems in the common empirical studies of crime cast doubt on a substantial part of this literature.

Most empirical studies are plagued by substantial underregistration of crime. Registration depends on the attitude of those who discover a crime, on the access to telephone, on insurance, on police routines, etc. If recording differs between police districts (in cross section studies) or over the years (in time series studies), a spurious negative correlation will appear between the crime rate and the proportion of crimes that are cleared up (see e.g. Blumstein et al., 1978): If, on the other hand, an increase in the number of policemen increases the number of crimes that are formally recorded, but not cleared up, there will be a spurious negative correlation between the number of policemen and clear-up proportion. Thus, underreporting and changes in recording will usually introduce a bias in favour of deterrence, but against the hypothesis that the police produces it (Cameron 1988). These spurious correlations impede the evaluation of criminometric studies, that most often confirm that crime increases with a decrease in the clear-up proportion, but that more police does not increase the clear-up proportion. This difficulty has inspired us to deal more explicitly with measurement errors. Especially, we introduce latent variables and employ the maximum likelihood method in estimating the structural relations of a simultaneous model.

Fisher and Nagin (1978) have discussed the serious problem of identification of models of crime. They are reluctant to accept the commonly used procedure in empirical crime studies of identifying models by excluding various socioeconomic variables from the equations. Using panel data we have succeeded in identifying our model by showing that the structural parameters are explicit functions of the theoretical 2. order moments of the crime and clear-up rates.

This paper is meant to be the first step in a more comprehensive criminometric study. When designing the model, we have emphasized simplicity in order to focus on some basic theoretical and empirical issues. In particular, we have not included sociodemographic variables explicitly. We include, however, latent police districts effects which summarize the effects of socioeconomic variables on crimes and on clear-ups, and we model the distributions of these latent variables across police districts and over time. The strength of sentences is not included as a variable, because no perceptible difference in this factor seems to exist between police districts and over time in the period studied.

The paper is organized as follows: In section 2 the criminometric model is derived by combining an equilibrium model of the latent number of crimes and clear-ups, based on behavioural relations of the offenders and the police, and measurement relations allowing for random and systematic measurement errors in the registered crimes and clear-ups. Furthermore, submodels and hypotheses are classified. Section 3 presents detailed and subtle identification results within this model class for panel data. Data and inference procedures are presented in section 4, and the empirical results in section 5 . The main conclusions are summarized in section 6.

## 2. MODEL AND HYPOTHESES

The criminometric model is designed to describe and explain crime and clear-up rates for $\mathrm{I}(\mathrm{i}=1,2, \ldots \mathrm{I})$ police districts in $\mathrm{T}(\mathrm{t}=1,2, \ldots, \mathrm{~T})$ years. Section 2.1 presents the equilibrium model of crimes and clear-ups based on behavioural relations between the true latent variables. In section 2.2 we introduce measurement relations connecting the true latent variables with the observed crimes and clear-ups. The criminometric model in final form, derived from the submodels in 2.1 and 2.2 , is
given in section 2.3, and in section 2.4 we define submodels and present hypotheses to be tested. Note that the equations below hold for all relevant $i$ and t.

### 2.1. An equilibrium model of crimes and clear-ups

The equilibrium model consists of the following three equations:

$$
\begin{equation*}
P_{i t}=Y_{i t} / X_{i t} \tag{1a}
\end{equation*}
$$

$X_{i t}=P_{i t}^{b} C_{i t}$,
$Y_{i t}=X_{i t}^{r} U_{i t}$.
$\mathrm{X}_{\mathrm{it}}$ is the (true) crime rate, i.e. the number of crimes per 1000 inhabitants, in police district i in year t . $\mathrm{Y}_{\mathrm{it}}$ is the clear-up rate defined as the number of clear-ups per 1000 inhabitants. $\mathrm{P}_{\mathrm{it}}$ is the clear-up proportion defined in (1a), i.e. the number of clear-ups as a share of the number of crimes. (In the literature this concept ( $\mathrm{P}_{\mathrm{it}}$ ) is sometimes denoted "clear-up rate", while we prefer to use this term to denote the concept symbolized by $\mathrm{Y}_{\mathrm{it}}$, treating crimes and clear-ups "symmetrically" throughout the analysis.)

The crime function (1b) says that the crime rate $\left(\mathrm{X}_{\mathrm{it}}\right)$ is a simple power function of the clear-up proportion ( $\mathrm{P}_{\mathrm{it}}$ ). It can be interpreted as a behavioural relation for an average offender with rational expectations on the probability of being caught. Furthermore, it can be derived from a utility maximizing model in the tradition of Becker (1968), keeping the severity of punishment constant. For convenience we will call the parameter $b$ the deterrence elasticity and the variable $C_{i t}$ the crime tendency in police district $i$ in year $t$. The crime tendency ( $C_{i t}$ ) summarizes the effect of the socioeconomic environment and other variables not explicitly modelled. The distribution of these latent crime tendencies across districts and over time will be modelled below.

The clear-up function (1c) says that the clear-up rate $\left(Y_{i t}\right)$ is a simple power function of the crime rate $\left(\mathrm{X}_{\mathrm{it}}\right)$. It can be interpreted as a behavioural relation of
the police. One may also interpret it as a combined relation of the behaviour of the police and the political authorities financing the police force. For convenience we will call the parameter r the clear-up elasticity, and the variable $\mathrm{U}_{\mathrm{it}}$ the clear-up tendency.

We will below interpret, exploit, and/or test the following hypotheses on the deterrence elasticity (b) and the clear-up elasticity (r):
(a) $b<0$,
(b) $r>0$,
(c) $\mathbf{r}<1$,
(d) $d \equiv 1+b(1-r)>0$.

The theory of Becker (1968) implies (2a). Relation (2b) seems reasonable because more crimes make it possible to get more cases cleared up. With more crimes, however, less police force would be available per case, thus (2c) seems plausible. Restriction (2d) secures that there will exist a meaningful and stable solution to our equilibrium model. (The significance of the sign of the "stability parameter" $d$ is discussed below.) Assuming (2c), the restriction (2d) is equivalent to $b>-1 /(1-r)$, i.e. the deterrence elasticity must not, for a fixed value of $r$, be too negative. Furthermore, from (2a),.(2c), and (2d) it follows that
$0<d<1$.

The system of equations (1) has three endogenous variables ( $\mathrm{P}_{\mathrm{it}}, \mathrm{X}_{\mathrm{it}}, \mathrm{Y}_{\mathrm{it}}$ ), and two exogenous variables $\left(\mathrm{C}_{\mathrm{it}}, \mathrm{U}_{\mathrm{it}}\right)$, with the following solution:

$$
\begin{align*}
& P_{i t}=C_{i t}^{(r-1) / d} U_{i t}^{1 / d}  \tag{3a}\\
& X_{i t}=C_{i t}^{1 / d} U_{i t}^{b / d}  \tag{3b}\\
& Y_{i t}=C_{i t}^{r / d} U_{i t}^{(1+b) / d} \tag{3c}
\end{align*}
$$

Assuming (2), we obtain clear-cut sign results in five out of six cases: Increased crime tendency ( $\mathrm{C}_{\mathrm{it}}$ ) decreases the clear-up proportion ( $\mathrm{P}_{\mathrm{it}}$ ), increases the crime rate ( $\mathrm{X}_{\mathrm{it}}$ ) and increases the clear-up rate ( $\mathrm{Y}_{\mathrm{it}}$ ). Increased clear-up tendency ( $\mathrm{U}_{\mathrm{it}}$ )
increases the clear-up proportion ( $\mathrm{P}_{\mathrm{it}}$ ), and reduces the crime rate ( $\mathrm{X}_{\mathrm{it}}$ ), whereas the sign effect on the clear-up rate depends on the magnitude of the deterrence effect:

$$
\begin{equation*}
\mathrm{El}_{\mathrm{U}_{\mathrm{it}}} \mathrm{Y}_{\mathrm{it}}=(1+\mathrm{b}) \mathrm{d} \underset{<}{\frac{\geq}{<}} 0 \quad \text { iff } \mathrm{b} \frac{\geqq}{<}-1 . \tag{4}
\end{equation*}
$$

Thus, if the deterrence elasticity is less than -1 , an increased clear-up tendency $\left(U_{i t}\right)$ reduces the number of clear-ups ( $Y_{i t}$ ) due to the strong reduction in the number of crimes.

The question of stability of the equilibrium solution (3) can most easily be discussed by help of Fig. 1, where the crime rate is measured along the horizontal axis, and the clear-up proportion along the vertical one. (For convenience, the subscripts $i$ and $t$ are here dropped.) The crime curves illustrate relation (1b) when $b<0, c f(2 a)$. The crime control curves are obtained by eliminating the clear-up rate through substitution of (1c) into (1a):
$P_{i t}=X_{i t}^{r-1} U_{i t}$, or
$X_{i t}=P_{i t}^{\frac{1}{r-1}} U_{i t}^{\frac{1}{1-r}}$.

Relation ( $1 c^{\prime}$ ) can be interpreted as the crime control function of the society (including the police). The clear-up activity represented by (1c) has been transformed into a function determining the clear-up probability (which again, in interaction with the crime function, determines the equilibrium values of the model).

In Fig. 1 we assume that there exist positive equilibrium values $P^{*}$ and and $X^{*}$ of the clear-up proportions and crime rates, respectively, and that (2a) and (2c) are satisfied. In Fig. 1 (a) the crime curve is steeper than the crime control curve, which means, $\mathrm{cf}(1 \mathrm{~b})$ and $(1 \mathrm{c}$ ), that $1 /(r-1)<b$, or $1+b(1-r)>0$, which is the same as restriction (2d). Considering, according to the correspondence-principle of Samuelson (1945), our equilibrium to be the stationary solution to a corresponding dynamic model, where the society (including the police) determines the clear-up probability ( $\mathrm{cf}\left(1 \mathrm{c}^{\prime}\right)$ ), and the potential offenders thereafter determines the number

Fig. 1 Stability of equilibrium
of crimes (cf(1b)), the following mechanism is obtained: If we start out with a hypothetical crime rate X 1 , the society's crime control ( $\mathbf{c f}\left(1 \mathbf{c}^{\prime}\right)$ ) will result in a clear-up rate P 1 , a rate at which crime ( $\mathrm{cf}(1 \mathrm{~b})$ ) will be reduced to X 2 , which again will result in a higher clear-up rate P2, etc. The crime rate and the clear-up proportion will move towards the equilibrium solution. A similar move towards equilibrium will obtain if we start from a crime rate below its equilibrium value. Thus, restriction (2d) is sufficient for a stable equilibrium under the stated conditions. If $\mathrm{d}<0$, we have the situation in Fig. 1 (b). Here, the society's crime control activity will produce, from a hypothetical crime rate X3, say, a clear-up proportion P 3 , that will result in a higher crime rate X 4 , which again will produce a lower clear-up proportion P4, etc. The crime rate will explode. Starting with any crime rate below $\mathrm{X}^{*}$, the clear-up proportion will increase and the crime rate decrease. With our assumptions, we thus find that ( 2 d ) is also a necessary condition for the equilibrium solution to be stable. (If $\mathrm{d}=0$ the two curves merge,
and no single equilibrium solution is obtained.) It is straightforward to formally prove stability by analyzing an appropriate difference equation.

The model determines an equilibrium for each police district in every year. By specifying a distribution on the crime and clear-up tendencies ( $\mathrm{C}_{\mathrm{it}}, \mathrm{U}_{\mathrm{it}}$ ) across police districts, and how it varies over time, we obtain a corresponding distribution of crimes and clear-ups ( $X_{i t}, Y_{i t}$ ) through the reduced form model (3). We will give a full specification later. As for now, we introduce the following decomposition:
$\ln C_{i t}=\omega_{0 t}+\omega_{1 i}+t \omega_{2 i}$,
$\ln U_{i t}=\lambda_{0 t}+\lambda_{1 i}+t \lambda_{2 i}$,
where $\omega_{0 \mathrm{t}}$ and $\lambda_{0 \mathrm{t}}$ are deterministic (police district invariant) time trends, and the remaining $\omega s$ and $\lambda s$ are time invariant latent district effects. This structure allows for a restricted evolution over time in the distribution of the crime and clear-up tendencies across police districts.

### 2.2. Measurement relations

Let $x_{i t}$ and $y_{i t}$ be the logs of the registered crime and clear-up rates, respectively. These are related to the true rates by the following equations:

$$
\begin{align*}
& x_{i t}=\ln X_{i t}+e_{t}+\varepsilon_{i t}  \tag{6a}\\
& y_{i t}=\ln Y_{i t}+f_{t}+\varphi_{i t} \tag{6b}
\end{align*}
$$

Here, $\exp \left(e_{t}\right)$ and $\exp \left(f_{t}\right)$ represent systematic, multiplicative measurement errors in $\exp \left(x_{i t}\right)$ and $\exp \left(y_{i t}\right)$, respectively. The terms $e_{t}$ and $f_{t}$ are police district invariant, but may change over time. The term $e_{t}$ takes account of the problem of systematic underreporting (dark number) of crime. The variables $\varepsilon_{i t}$ and $\varphi_{i t}$ can be interpreted as random measurement errors.

For convenience we define the following transformed variables:

$$
\begin{align*}
& \chi_{i t}=\ln X_{i t}+e_{t}  \tag{7a}\\
& \Psi_{i t}=\ln Y_{i t}+f_{t} \tag{7b}
\end{align*}
$$

$$
\begin{align*}
& \pi_{i t}=\psi_{i t}-\chi_{i t}  \tag{7c}\\
& a_{t}=\omega_{0 t}+(1+b) e_{t}-b f_{t},  \tag{7d}\\
& k_{t}=\lambda_{0 t}-r e_{t}+f_{t} . \tag{7e}
\end{align*}
$$

In (7a) we define the $\log$ of the latent crime rate $\left(\chi_{i t}\right)$ as the sum of the $\log$ of the true crime rate ( $\mathrm{X}_{\mathrm{it}}$ ) and the systematic measurement error $\left(\mathrm{e}_{\mathrm{t}}\right)$. The $\log$ of the latent clear-up rate ( $\Psi_{\mathrm{it}}$ ), and the $\log$ of the latent clear-up proportion ( $\pi_{\mathrm{it}}$ ) are defined in (7b) and (7c). The parameters $a_{t}$ and $k_{t}$ are introduced in order to simplify the criminometric model below. Note that $a_{t}$ and $k_{t}$ are composed of the deterministic time trends of (5) and (6). We do not try to identify and estimate these components separately.

### 2.3. The criminometric model in final form

From (1), (5), (6), and (7) we can now derive the following criminometric model:
$x_{i t}=\chi_{i t}+\varepsilon_{i t}$,
$y_{i t}=\psi_{i t}+\varphi_{i t}$,
$\pi_{i t}=\psi_{i t}-\chi_{i t}$,
$\chi_{i t}=b \pi_{i t}+a_{t}+\omega_{1 i}+t \omega_{2 i}$,
$\Psi_{i t}=r \chi_{i t}+k_{t}+\lambda_{1 i}+t \lambda_{2 i}$.

We assume the following stochastic specification:
$\mathrm{E} \varepsilon_{i t}=\mathrm{E} \varphi_{i t}=\mathrm{E} \omega_{1 \mathrm{i}}=\mathrm{E} \omega_{2 \mathrm{i}}=\mathrm{E} \lambda_{1 \mathrm{i}}=\mathrm{E} \lambda_{2 \mathrm{i}}=0$,
$E \varepsilon_{i t}^{2}=\sigma_{\varepsilon \varepsilon}, \quad E \varphi_{i t}^{2}=\sigma_{\varphi \varphi}, \quad E \varepsilon_{i t} \phi_{i t}=\sigma_{\varepsilon \varphi}$,
$E \omega_{1 \mathrm{i}}^{2}=\sigma_{\omega 1 \omega 1}, \quad E \omega_{2 \mathrm{i}}^{2}=\sigma_{\omega 2 \omega 2}, \quad \mathrm{E} \omega_{1 i} \omega_{2 \mathrm{i}}=\sigma_{\omega 1 \omega 2}$,
$E \lambda_{1 \mathrm{i}}^{2}=\sigma_{\lambda 1 \lambda 1}, \quad E \lambda_{2 \mathrm{i}}^{2}=\sigma_{\lambda 2 \lambda 2}, \quad E \lambda_{1 \mathrm{i}} \lambda_{2 \mathrm{i}}=\sigma_{\lambda 1 \lambda 2}$,
and all other covariances between the exogenous variables ( $\varepsilon, \varphi, \omega$, and $\lambda$ ) are assumed to be zero. Note that the assumptions of (9a) are innocent because of the
constant terms defined in (5) and (6). Note, too, that the random measurement errors ( $\varepsilon_{i t}$ and $\varphi_{i t}$ ) are allowed to be correlated. We expect this correlation to be positive: If, in a police district, registration is particularly sloppy, some crimes that elsewhere normally would have resulted in separate files, are only informally recorded. As formal files, including eventual clear-ups, constitute the basis for the production of statistics, both the registered numbers of crimes and the registered number of clear-ups will be lower than in a similar police district with better registration procedures. This underregistration results in a positive correlation between the random measurement errors. The same will happen if some files are forgotten when statistics are produced by the end of the year.

### 2.4. Hypotheses and model specifications

Various specifications of the model (8)-(9) can be estimated by use of our panel data. A classification of assumptions which may be combined in various manners in order to obtain different models, is found in Table 1. Each assumption is given a label, and each model will be denoted by the corresponding combination of labels. (See Aasness, Biørn, and Skjerpen (1988) for a similar framework.) The assumptions correspond to some of the hypotheses we are interested in testing, especially hypotheses about the correlation of measurement errors, and about the distributions of latent police district effects. On the basis of the model classification of Table 1 it is possible to specify $2 \times 4 \times 4=32$ different models defined by different assumptions in the M-, W- and L-dimensions, where these dimensions refer to correlations of measurement errors (M), correlations of police district effects on crimes (W), and correlations of police district effects on clear-ups (L). All these specific models are estimated and/or tested in the empirical analysis. We could, of course, introduce other specifications, e.g. time trends in the police district invariant terms $a_{t}$ and $k_{t}$, but this is not carried out in the present paper.

## 3. IDENTIFICATION

Identification of most of the submodels are proven by showing that the structural parameters are explicit functions of the theoretical 2. order moments of the crime and clear-up rates, see Appendix $B$. The results of our investigation of
identification are summarized in Table 2. Here $\mathrm{Wi}^{*}(\mathrm{i}=0,1,2,3$ ) denotes the same assumptions as Wi in Table 1, except that all parameters assumed to be free in Table 1 now are assumed not to be zero. $\mathrm{Lj}^{*}$ is defined similarly, and we have, for instance, that $\mathrm{W} 1^{*} \mathrm{~L} 0$ corresponds to W 1 L 0 , the difference being that $\sigma_{\omega 1 \omega 1}$ can be zero in the latter, but not in the former. Table 2 thus contains a complete set of submodels of W3L3.

Table 1
Classification of hypotheses and models ${ }^{\text {a }}$

| Assumptions with respect to correlations of measurement errors |  |  |
| :--- | :---: | :--- |
| Label | Parameter restriction | Interpretation |
|  | $\sigma_{\varepsilon \varphi}$ |  |
| M0 | 0 | No correlation of measurement errors |
| M1 | free | Measurement errors correlated |

Assumptions with respect to correlations of police district effects on crimes

| Label | Parameter restriction |  |  | Interpretation |
| :---: | :---: | :---: | :---: | :--- |
|  | $\sigma_{\omega 1 \omega 1}$ | $\sigma_{\omega 2 \omega 2}$ | $\sigma_{\omega 1 \omega 2}$ |  |
| W0 | 0 | 0 | 0 | No district effect in crime |
| W1 | free | 0 | 0 | Time invariant district effect in crime |
| W2 | free | free | 0 | Trend in distribution of district effect in crime |
| W3 | free | free | free | Time invariant and trend effects correlated |

Assumptions with respect to correlations of police district effects on clear-ups

| Label | Parameter restriction |  |  | Interpretaion |
| :---: | :---: | :---: | :---: | :--- |
|  | $\sigma_{\lambda 1 \lambda 1}$ | $\sigma_{\lambda 2 \lambda 2}$ | $\sigma_{\lambda 1 \lambda 2}$ |  |
| L0 | 0 | 0 | 0 | No district effect in clear-ups |
| L1 | free | 0 | 0 | Time invariant district effect in clear-up |
| L2 | free | free | 0 | Trend in distribution of district effect in clear-up |
| L3 | free | free | free | Time invariant and trend effects correlated |

[^1]A particular problem arises in models W3 ${ }^{*} \mathrm{~L} 3^{*}$ and $\mathrm{W} 2{ }^{*} \mathrm{~L} 2^{*}$. Here identification of $r$ (or b) requires the solution of a second order equation in this parameter, and we will in general have two different roots, corresponding to two observationally equivalent structures. The model can nevertheless be identified if only one of the two solutions satisfy a priori restrictions on the set of parameter values. The simplest case is to assume (2e), i.e. $0<d<1$, since we have shown (Appendix B.10) that only one of the two solutions can satisfy this restriction.

If one is not willing to use (2e) as a maintained assumption, for example because one is interested in testing this hypothesis, or the hypothesis of $b<0$, there are still possibilities for discriminating between the two observationally equivalent structures, combining a priori and empirical information. We will give an example of this. Consider the following set of restrictions, $\mathrm{cf}(2 \mathrm{~b})$ and (2d):

Table 2
Identification of submodels of W3L3 ${ }^{\text {ab }}$

|  | W3* | W2 ${ }^{*}$ | W1 ${ }^{*}$ | W0* |
| :---: | :---: | :---: | :---: | :---: |
| L3* | Identified if assuming (2e) or \#A=1 | Identified | Identified | Not identified ${ }^{\text {c }}$ |
| L2 * | Identified | Identified if assuming (2e) or \#A=1 | Identified | Not identified ${ }^{\text {c }}$ |
| L1 ${ }^{*}$ | Identified | Identified | Not identified ${ }^{\text {e }}$ | Not identified ${ }^{\text {c }}$ |
| L0* | Not identified ${ }^{\text {d }}$ | Not identified ${ }^{\text {d }}$ | Not identified ${ }^{\text {d }}$ | Not identified |

[^2]$\Theta=\left\{\theta \in \mathrm{R}^{\mathrm{n}} \mid \Sigma_{\omega \omega}, \Sigma_{\lambda \lambda}\right.$, and $\Sigma_{\varepsilon \varphi}$ are all positive semidefinit, $\left.\mathrm{r}>0, \mathrm{~d}>0\right\}$,
where $\theta$ are the unknown parameters of our model, and
\[

\Sigma_{\omega \omega}=\left[$$
\begin{array}{ll}
\dot{\sigma}_{\omega 1 \omega 1} & \sigma_{\omega 1 \omega 2} \\
\sigma_{\omega 1 \omega 2} & \sigma_{\omega 2 \omega 2}
\end{array}
$$\right], \quad \Sigma_{\lambda \lambda}=\left[$$
\begin{array}{ll}
\sigma_{\lambda 1 \lambda 1} & \sigma_{\lambda 1 \lambda 2} \\
\sigma_{\lambda 1 \lambda 2} & \sigma_{\lambda 2 \lambda 2}
\end{array}
$$\right], \quad \Sigma_{\varepsilon \varphi}=\left[$$
\begin{array}{ll}
\sigma_{\varepsilon \varepsilon} & \sigma_{\varepsilon \varphi} \\
\sigma_{\varepsilon \varphi} & \sigma_{\varphi \varphi}
\end{array}
$$\right] .
\]

Let $\Sigma(\theta)$ denote the theoretical covariance matrix of the observed variables as a function of the unknown parameters $\theta$ of our model. Let
$A=\left\{\theta \in R^{\mathrm{n}} \mid \Sigma(\theta)=\Sigma\right\} \cap \Theta$
for an arbitrary value of the covariance matrix $\Sigma$. If, for a given model, the number of elements in $A$ is equal to one (\#A=1), we consider the corresponding solution the only one that can be accepted. The number of elements in A can depend on $\Sigma$, and the question of identification of $\mathrm{W} 3^{*} \mathrm{~L} 3^{*}$ and $\mathrm{W} 2^{*} \mathrm{~L} 2^{*}$ thus involves empirical issues. In the empirical analysis below we argue that only one of the two solutions of $\mathrm{W} 3^{*} \mathrm{~L} 3^{*}$ is relevant in our case.

It is demonstrated in Appendix B (Section B.9) that, $\mathrm{Wi}^{*} \mathrm{Lj}^{*}$ is observationally equivalent to $W_{j}{ }^{*} L_{i}{ }^{*}$ for $i \neq j$ and $i, j=0,1,2,3$. Restriction (10) will in some of these cases determine which of two "symmetric" models is relevant or acceptable. Furthermore, it is shown that assuming (2e) for one such model, the symmetric one is unstable, i.e. $d<0$. That is, within the set of two symmetric models $\left\{\mathrm{Wi}^{*} \mathrm{Lj}^{*}\right.$, $\left.\mathrm{Wj}^{*} \mathrm{Li}^{*}\right\}(\mathrm{i} \neq \mathrm{j}, \mathrm{i}, \mathrm{j}=1,2,3$ ), we can identify the correct model under assumption (2e).

The parameters $\sigma_{\varepsilon \varepsilon}, \sigma_{\varphi \varphi}$, and $\sigma_{\varepsilon \varphi}$ are identified for W3L3 as a whole. Six of the submodels are completely identified. Identification of $b$ is further obtained in the three first models of the last column, whereas identification of the remaining parameters here requires one supplementary piece of information (e.g. fixing the value of one of them). Similarly, $r$ is identified in the three first models of the last line, and here too one more piece of information is necessary in order to identify the remaining parameters.

## 4. DATA AND ESTIMATION

The model is estimated by use of data on the number of crimes and clear-ups for 53 police districts in Norway for the period 1970-78, (cf Central Bureau of Statistics, annual). Our main reasons for choosing this period is the absence of substantial changes in legal rules or registration practices, and the wish to make comparisons with Eide (1987). These data are transformed into crime rates and clear-up rates (Tables A3 and A5) and further into logs of these rates (Tables A7 and A8). Finally, the logs are used to calculate a covariance matrix of the $\log$ numbers of crime and clear-up rates for the nine years. This covariance matrix (see Appendix A) is all the data we use in our econometric analysis.

Let $\mathbf{S}$ be this sample covariance matrix of our observed variables, and
$F=\ln |\Sigma(\theta)|+\operatorname{tr}\left(S \Sigma(\theta)^{-1}\right)-\ln |S|-2 T$,
where "tr" is the trace operator, i.e. the sum of the diagonal elements of the matrix.

Minimization of $F$ w.r.t. $\theta$ is equivalent to maximization of the likelihood function when assuming that all the observed variables (i.e. the lnx's and lny's) are multinormally distributed. (All the first order moments are used to estimate the constant terms $\mathrm{a}_{\mathrm{t}}$ and $\mathrm{k}_{\mathrm{t}}$.) We have used the computer program LISREL 7 by Jöreskog and Sörbom (1988) to perform the numerical analysis.

A standard measure of the goodness of fit of the entire model in LISREL is GFI $=1-\operatorname{tr}\left[\left(\Sigma^{-1} \mathrm{~S}-\mathrm{I}\right)^{2}\right] / \operatorname{tr}\left[\left(\Sigma^{-1} \mathrm{~S}\right)^{2}\right]$, where I is the identity matrix; GFI $=1$ indicates perfect fit. Standard asymptotic $t$-values and $\chi^{2}$ - statistics are utilized. We use a significance level of 0.01 as a standard in our test, but report also significance probabilities.
We will test a specific model 0 (the null hypothesis) against a more general model 1 (the maintained hypothesis) by a likelihood ratio test. Let $\mathrm{F}_{0}$ and $\mathrm{F}_{1}$ be the minimum of $F$ under model 0 and model 1 , respectively, and let $s$ be the difference in the number of parameters of the two models. It can be shown that minus twice the logarithm of the likelihood ratio is equal to $I\left(F_{0}-F_{1}\right)$, where $I$ is the number of police districts. According to standard theory this statistic is
approximately $\chi^{2}$ distributed with $s$ degrees of freedom. The $\chi^{2}$ value for each model, given in Table 3, is defined as $\mathrm{IF}_{0}$, which can be interpreted as the test statistic above when the alternative hypothesis is an exactly identified model, giving a perfect fit to the sample covariance matrix and accordingly $\mathrm{F}_{1}=0$. The test statistic $\mathrm{I}\left(\mathrm{F}_{0}-\mathrm{F}_{1}\right)$ for an arbitrary pair of models may thus be computed by simply subtracting the corresponding pair of $\chi^{2}$ values. The significance probability corresponding to the value of a test statistic, i.e. the probability of getting a $\chi^{2}$ value greater than the value actually obtained given that the null hypothesis is true, is reported in Table 4.

LISREL 7 minimizes the function $F$ without imposing any constraints on the admissible values of the parameter vector $\theta$. Thus the LISREL estimate of a parameter which we interpret as a variance, may well turn out to be negative. This may be considered as a drawback of this computer program. However, if our model and its interpretation is correct, the LISREL estimates should turn out to have the expected signs, apart from sampling errors. Thus, if for a given model all the estimated variances are positive, and all the estimates of the covariance matrices $\Sigma_{\omega \omega}, \Sigma_{\lambda \lambda}$, and $\Sigma_{\varepsilon \varphi}$ are positive semidefinite, we will take this as a confirmation that the model has passed an important test. This in fact happened in our empirical analysis.

If one is unwilling to assume normality of the observed variables, the estimators derived from minimizing $F$ above can be labelled quasi maximum likelihood estimators. These estimators will be consistent, but their efficiency and the properties of the test procedures are not so obvious. A large literature on the robustness of these types of estimators and test procedures for departure from normality prevails, see e.g. Jøreskog and Sørbom (1988) for an extensive list of references, with quite different results depending on the assumptions and methods used. A recent and growing literature shows, however, that the estimators and test statistics derived under normality assumptions within LISREL type of models retain their asymptotic properties for wide departures from normality, exploiting assumptions on independently distributed nonnormal latent variables, see e.g. Anderson and Amemiya (1988), Amemiya and Anderson (1990), Browne (1987), and Browne and Shapiro (1988).

The assumption of normality can be tested by use of the (moment coefficient of) skewness $\mathrm{m}_{3} / \sqrt{\mathrm{m}_{2}}{ }^{3}$ and the (moment coefficient of) kurtosis $\mathrm{m}_{4} / \mathrm{m}_{2}{ }^{2}$. In a normal distribution the skewness is equal to zero, and the kurtosis is equal to three. Given that the distribution is normal, the observed skewness and kurtosis are asymptotically independent, and can thus be used for two asymptotically independent tests of normality. Skewness and kurtosis for our samples have been calculated (by SPSS) for the crime and clear-up rates, and for their logs, and are included in Tables A3-A8. In 98\% of all samples of size 50 from a normal population we have that the absolute value of skewness is less than 0.787 , and the value of kurtosis is within the interval $[1.95,4.88]^{2}$. We find that normality is rejected for the crime rate (Table A3) by the skewness test for all years, and by the kurtosis test for two years. As for the clear-up rate (Table A5), normality is rejected by both tests for all years. The log of crime rates (Table A7) passes the skewness test for all years, but the kurtosis test for none, whereas the log of clearup rates (Table A8) passes the skewness test in three years, and the kurtosis test also in three years. Obviously, a logarithmic specification of our model is to be preferred to a linear one. The values of the observed kurtosis are low, indicating platykurtic or "flat" distributions. This departure from normality is considered in the $\chi^{2}$ tests below.

As the distribution of the logs of the crime and clear-up rates are found to be platykurtic this $\chi^{2}$ test may not be satisfactory. However, the test can easily be corrected by dividing the difference of the corresponding pairs of $\chi^{2}$ values by the relative multivatiate kurtosis when performing the significance test. As the relative multivariate kurtosis for our covariance matrix is very close to one (1.06), the results of the likelihood ratio tests are not changed by this adjustment, and we find it unneccessary to present details.

## 5. EMPIRICAL RESULTS

### 5.1. Likelihood ratio tests

All 32 models classified in Table 1 have been fitted. Table 3 contains for all models

[^4]the degrees of freedom (df), the goodness of fit (GFI), and the likelihood ratio $\chi^{2}$ test statistic for each model against a model with no restriction on the covariance
matrix.
First, we have studied the presence of correlation of measurement errors by testing M0 against M1. For all (16) possible combinations of maintained assumptions in the W - and L-dimensions MO is rejected, even at a level of significance of $10^{-6}$.

Table 4.1 presents significance probabilities for tests of each of the hypotheses in the W-dimension against a more general hypothesis of the same dimension. These tests are performed for each of the alternative maintained assumptions in the L-dimension. Table 4.2 contains similar tests of the L-dimension. From Tables 4.1 and 4.2 we conclude that the hypotheses of $\mathrm{W} 0, \mathrm{~L} 0, \mathrm{~W} 1$, and L1 are rejected. We have further found (not included in Table 4) that WOLO is rejected against W1L1, W1L1 against W2L2, and W2L2 against W3L3. This leaves us with the general model M1W3L3 and the two non-rejected models M1W3L2 and M1W2L3. The choice between them can be made on the basis of parsimony, and of the acceptability of the estimated parameters. It will be argued below that M1W3L2 is the model to be preferred.

### 5.2. Evaluation of models not rejected by likelihood ratio tests

As identification of certain parameters in some of our models depends on the solution of a second order equation, there will in general exist two observationally equivalent structures, and correspondingly two global minima to the fit function in (11). Depending on the starting values, LISREL will find one or the other of these two solutions. The second one, which has the same F-value as the first, can be located by choosing appropriate starting values. This is done for the model M1W3L3, where we obtain the solutions I and II, the parameter estimates of which are given in Table 5. The two solutions are further characterized in Fig. 2, where the minimum value of $F$ is plotted for various given values of $r$. The two global minima of $F$ are obtained for those values of $r$ that correspond to the solutions I and II. As a check of our conclusions, the minimum value of $F$ has been calculated for a series of values of $r$ in the interval $[-200,200]$. $F$ is decreasing for values of $r$ to the left of the lower solution. For values of $r$ higher than 1.7, $F$ is decreasing, but very slowly, and does not reach lower than 2.752 in the interval studied.

[^5]

Fig. 2. F-values of M1W3L3 with two solutions

Solution II violates restrictions (2b) and (2d), cf (10), whereas all the estimates in solution I seem sensible. Thus, we prefer solution I.

We observe that the estimates of M1W3L3 ${ }^{I}$ and M1W3L3 ${ }^{\text {II }}$ are almost identical with those of M1W3L2 and M1W2L3, respectively. Furthermore, from the estimates of $b$ and $r$ we calculate the value of the stability parameter $d$ to be 0.83 in M1W3L2 and -4.99 in M1W2L3. Thus we prefer the former model to the latter, cf section 3. The final choice is then between M1W3L3 ${ }^{I}$ and M1W3L2. The latter being more parsimonious, we consider this model to be the preferred one. We focus on this model in sections 5.3 to 5.5 , and discuss robustness of results across models in section 5.6.

### 5.3. The deterrence and clear-up elasticities

The estimate of the deterrence elasticity (b) is significantly negative in our preferred model, and close to -1. The estimate of the clear-up elasticity ( $r$ ) is about 0.8 in our preferred model, and the confidence interval is clearly within the boundaries argued a priori, cf (2). These estimates of $b$ and $r$ imply that the estimate of the stability parameter d is 0.8 , and the corresponding confidence interval is clearly within the boundaries ( 0,1 ), in agreement with our hypothesis (2e).

[^6]
### 5.4. Distribution of crime and clear-up tendencies

The estimates of the distribution parameters of the district effects on crime are also given in Table 5. Straightforward calculation shows that for our preferred model the variance of the crime tendency, var $\ln C_{i t}=\sigma_{\omega 1 \omega 1}+t^{2} \sigma_{\omega 2 \omega 2}+2 t \sigma_{\omega 1 \omega 2}$, is estimated to be positive for all years, i.e. for $t=1,2, \ldots, 9$. As this estimate is not restricted to positive values by LISREL, we take the result as a confirmation that our model, and our interpretation of it, has passed an interesting test.

We note that $\sigma_{\omega 1 \omega 2}$ is significantly negative. Furthermore, the estimates indicate a decrease in the variance of the district effects over time. Denoting the first difference operator by $\Delta$, we see in fact that $\Delta v a r \ln C_{i t}=2(t-1) \sigma_{\omega 2 \omega 2}+2 \sigma_{\omega 1 \omega 2}$ is negative for the whole period. The estimate of var $\ln \mathrm{C}_{\mathrm{it}}$ is, in this period, reduced from 0.250 to 0.186 . The estimate of the variance of the crime tendency is thus substantially reduced during the period.

The estimates of the variances of the district effects on clear-ups ( $\sigma_{\lambda 1 \lambda 1}$ and $\sigma_{\lambda 2 \lambda 2}$ ) are positive, as expected, and significantly different from zero in our preferred model. The change over time in the variance of the clear-up tendency is negligible.

### 5.5. Measurement errors

The estimates of the variances and the covariance of the errors of measurement are positive and highly significant. This confirms our hypothesis in section 2.4 of a positive $\sigma_{\varepsilon \varphi}$.

### 5.6. Robustness of results

Table 6 show the estimates of all models with two global maxima (solutions I and II). We observe that for all four solutions II the estimates of both $\mathbf{r}$ and $\mathbf{d}$ are negative. These models are thus rejected according to (10).

Tables 7 and 8 contain the estimates of all identified M1- and M0-models, respectively (solutions II not included). The M0-models are strongly rejected against the corresponding M1-models, and we may thus expect that at least some of the estimators of the structural parameters are biased in the M0-models. But no clear-cut results emerge by comparing Tables 7 and 8 . For example, the
estimates of $b$ and $r$ are rather close to each other for M1W3L3 and M0W3L3. For the latter, however, the estimate of the variance of $\lambda_{2}$ is negative, thus modelling measurement errors correctly can be important for estimating the other parameters.

Just like in our preferred model, the estimate of $b$ is found to be negative in all but 2 of the 16 estimated models in Tables 7 and 8. The two models in question, M1W2L1 and M1W3L1 have not significant estimates of $b$. They are strongly rejected by the likelihood ratio tests, and have some quite nonsensical estimates. Thus, we do not give them weight as evidence on $b$ : We conclude that the estimated sign of $b$ is robust across models, although the value varies substantially. This result suggests that misspecification in modelling may not hinder the sign of the deterrence elasticity to be correctly determined, but that a reliable estimate of its value requires thorough empirical analysis.

The estimate of $r$ is, as expected, and just as in our preferred model, located in the interval [ 0,1 ] for all 11 models where the estimate is significant. The estimate is positive in 3 of the remaining models, and negative in two, i.e. in M0W1L2 and M1W2L3. Of these, model M0W1L2 is firmly rejected. According to Table 4, M1W2L3 is not rejected against M1W3L3. We nevertheless disregard the former model, because the estimated value of $d$ is significantly negative, and because its symmetric counterpart M1W3L2 is perfectly acceptable. Thus, none of the more interesting models have estimates of $r$ that are outside the assumed interval.

For all models the variance of the crime tendency (var $\ln \mathrm{C}_{\mathrm{it}}$ ) is found to be positive in all years. We note that $\sigma_{\omega 1 \omega 2}$ is significantly negative for the fitted models where this parameter is not zero a priori (i.e. for the W3-models). Furthermore, the estimates indicate a decrease in the variance of the district effects over time for most models.

The estimates of the variances of the district effects on clear-ups ( $\sigma_{\lambda 1 \lambda 1}$ and $\sigma_{\lambda 2 \lambda 2}$ are positive in all models, but one. Here, in M0W3L3, the estimate of $\sigma_{\lambda 1 \lambda 1}$ is negative, but not significant.

The estimates of the variances and the covariance of the errors of measurement are very robust with respect to model specifications.

### 5.7. Estimate of MOW1L1

As shown in Table 2, model W1L1 cannot be identified without further restrictions.
In Table 9 we present the results when a constant value of $r$ is introduced as such a restriction. The table illustrates the effect of choosing various values of this parameter. We see that an increase in $r$ causes a strong decrease in the estimate

Table $9^{\text {a }}$

of $b$. The estimates of the measurement errors do not depend on the value of $r$. Observe that the $\chi^{2}$-value, as expected, is independent of $r$.

## 6. CONCLUSIONS

A new criminometric model is derived from a theory of criminal and police behaviour, and measurement relations with random and systematic registration errors. The effects of the socioeconomic environment are summarized by the latent district effects in the crime and clear-up functions, and the distribution of these latent variables across police districts and over time is modelled.

The model is not identified if the latent district effects are constant over time. If the latent district effects vary over time, many submodels are identified. In the
general model there will be two observationally equivalent structures, and correspondingly two global maxima in the likelihood function, due to the two solutions of a 2. order equation. However, by reasonable a priori restrictions in the parameter space, only one of the two solutions come out as empirically relevant.

The model was applied successfully on panel data on the number of crimes and clear-ups for the 53 police districts in Norway for 1970-78, confirming the hypothesis that our approach is fruitful. The model and the theoretical and empirical analysis can be extended in various ways. The present paper may thus be used as a starting point for further research in criminometrics.

The deterrence elasticity was found to be significantly negative and close to -1 . The estimate of this elasticity varies considerably between submodels, and illustrates the importance of our systematic approach to classifying, estimating, testing, and evaluating submodels.

The variance of the latent district effects in the crime function decreased during the period. The estimates of the variances and the covariance of the measurement errors were significantly positive and very robust with respect to model specifications.

## APPENDIX A: DATA

Data on the number of crimes in Table 2 is found in Central Bureau of Statistics (annual): Crime Statistics. Data on the number of clear-ups are unpublished statistics from the Central Bureau of Statistics.

A crime is registered by the police for statistical purposes in the year when the investigation is closed. Accordingly, the statistics give information on investigated cases and not about crimes committed in the statistical year. The average period of investigation has for the country as a whole and for all crimes taken together increased from 4 months in 1970-1972 to 4.9 months in the period 1980-1982. Cases shelved for observation are considered closed, but if such cases are subsequently cleared up, a new statistical report is submitted. If this happens the same year, the first report is not included in the statistics, but if it happens in a subsequent year, the crime is registered as a separate crime and clear-up that year.

The only noticeable legal change of some importance to the number of crimes during the studied period, was the decriminalizing of "naskeri" (petty larceny of less than about 50 kr .) by the end of 1972 . Until then this crime was included in the group of petty larceny, which accounted for about 30 per cent of total crimes. The number of crimes in this group did not decline from 1972 to 1973.

## APPENDIX B: IDENTIFICATION

## B.1. Introduction

Identification is proved by showing that the structural parameters are explicit functions of the theoretical 2 . order moments of the crime and clear-up rates. It turns out to be suitable to first deduce differences of the 2 . order moments, and general 2. order differences of the 2 . order moments of the crime and clear-up rates. Identification of $\sigma_{\varepsilon \varepsilon}, \sigma_{\varphi \varphi}$, and $\sigma_{\varepsilon \varphi}$ is proved for our most general model under investigation (M1W3L3), and for all its submodels. Then, identification of $\mathrm{r}, \mathrm{b}$ and the remaining variances and covariances is considered for various submodels. For two of these there exist two observationally equivalent structures. They may still be identified if one is willing to make restrictions in the parameter space as discussed in section 3 , and empirically analyzed in section 5 . It is further proved that full identification is not obtainable for some of the submodels. The 1. order moments are used to identify $a_{t}$ and $k_{t}$, whereas our assumption of normality excludes the possibility of obtaining supplementary information from moments of higher order than two.

## B.2. Derivation of 2. order moments

Omitting subscript $i$ for all variables we have for all $t$
(B1) $x_{t}=\chi_{t}+\varepsilon_{t}$,
(B2) $y_{t}=\Psi_{t}+\phi_{t}$,
(B3) $x_{t}=a_{t}+b \pi_{t}+\omega_{1}+t \omega_{2}$,
(B4) $\pi_{t}=\Psi_{t}-x_{t}$,
(B5) $\Psi_{t}=\mathrm{k}_{\mathrm{t}}+\mathrm{r} \chi_{\mathrm{t}}+\lambda_{1}+\mathrm{t} \lambda_{2}$.
Defining $\tilde{\chi}_{t}=\chi_{t}-E \chi_{t}$ etc., we obtain
(B1) $\tilde{x}_{t}=\tilde{\chi}_{t}+\varepsilon_{t}$,
(B2) $\tilde{\mathbf{y}}_{\mathbf{t}}=\tilde{\Psi}_{\mathbf{t}}+\boldsymbol{\phi}_{\mathbf{t}}$,
(B3) $\tilde{\boldsymbol{x}}_{\mathrm{t}}=\mathbf{b} \tilde{\pi}_{\mathrm{t}}+\omega_{1}+\mathbf{t} \omega_{2}$,
(B4) $\tilde{\pi}_{t}=\tilde{\Psi}_{t}-\tilde{\chi}_{t}$,
(B5) $\tilde{\Psi}_{t}=r \tilde{\chi}_{t}+\lambda_{1}+t \lambda_{2}$.
Substitution of (B4') and (B5') into (B3') gives
(B3*) $d \tilde{x}_{t}=\omega_{1}+t \omega_{2}+b\left(\lambda_{1}+t \lambda_{2}\right)$,
where $d=1+b(1-r)$ as defined in (2d).
Assuming $d \neq 0$, we have
(B3') $\tilde{x}_{t}=\frac{1}{d}\left(\omega_{1}+t \omega_{2}\right)+\frac{b}{d}\left(\lambda_{1}+t \lambda_{2}\right)$,
which substituted into (B5') gives
(B5') $\Psi_{t}=\frac{r}{d}\left(\omega_{1}+t \omega_{2}\right)+\frac{1+b}{d}\left(\lambda_{1}+t \lambda_{2}\right)$.
Substitution of (B3") into (B1'), and (B5") into (B2') gives
(B1') $\tilde{x}_{t}=\frac{1}{d}\left(\omega_{1}+t \omega_{2}\right)+\frac{b}{d}\left(\lambda_{1}+t \lambda_{2}\right)+\varepsilon_{v}$
and
(B2') $\tilde{y}_{t}=\frac{\mathrm{r}}{\mathrm{d}}\left(\omega_{1}+\mathrm{t} \omega_{2}\right)+\frac{1+\mathrm{b}}{\mathrm{d}}\left(\lambda_{1}+\mathrm{t} \lambda_{2}\right)+\phi_{\mathrm{t}}$.
For convenience we define
$K=\left(\frac{1}{d}\right)^{2}$.
Note that it follows from (2d) that $\mathrm{K}>0$.
From (B1") and (B2") we obtain, with the stochastic specifications assumed in 2.3 , the following second order moments for $\mathrm{t}, \mathrm{s}=1,2, \ldots, \mathrm{~T}$ :
(B6) $\operatorname{cov}\left(\mathrm{x}_{t}, x_{2}\right)=K\left[\sigma_{\omega_{1} \omega_{1}}+(t+s) \sigma_{\omega_{1} \omega_{2}}+t s \sigma_{\omega_{2} \omega_{2}}+b^{2} \sigma_{\lambda_{1} \lambda_{1}}+b^{2}(t+s) \sigma_{\lambda_{1} \lambda_{2}}+b^{2} t s \sigma_{\lambda_{2} \lambda_{2}}\right]+\delta_{t s} \sigma_{\varepsilon \varepsilon}$,
(B7) $\operatorname{cov}\left(y_{t}, y_{2}\right)=K\left[r^{2} \sigma_{\omega_{1} \omega_{1}}+r^{2}(t+s) \sigma_{\omega_{1} \omega_{2}}+r^{2} t s \sigma_{\omega_{2} \omega_{2}}\right.$

$$
\left.+(1+b)^{2} \sigma_{\lambda_{1} \lambda_{1}}+(1+b)^{2}(t+s) \sigma_{\lambda_{1} \lambda_{2}}+(1+b)^{2} t s \sigma_{\lambda_{2} \lambda_{2}}\right]+\delta_{t} \sigma_{\phi \phi},
$$

(B8) $\operatorname{cov}\left(\mathrm{X}_{\mathrm{t}}, \mathrm{y}_{8}\right)=\mathrm{K}\left[\mathrm{r} \sigma_{\omega_{1} \omega_{1}}+\mathrm{r}(\mathrm{t}+\mathrm{s}) \sigma_{\omega_{1} \omega_{2}}+\mathrm{rts} \sigma_{\omega_{2} \omega_{2}}\right.$

$$
\left.+(1+b) b \sigma_{\lambda_{1} \lambda_{1}}+(1+b) b(t+s) \sigma_{\lambda_{1} \lambda_{2}}+(1+b) b t s \sigma_{\lambda_{2} \lambda_{2}}\right]+\delta_{t z} \sigma_{e \phi},
$$

where $\delta_{\text {ts }}$ are Kronecker deltas.

## B.3. Differences of 2. order moments

We define, for all possible combinations of $i, j$, $t$, and $s$, the differences of 2 . order moments
(B9) $\Delta_{i j} \operatorname{cov}\left(x_{1}, x_{3}\right)=\operatorname{cov}\left(x_{1}, x_{7}\right)-\operatorname{cov}\left(x_{t-1} ; x_{3-j}\right)$,
and similarly for $\operatorname{cov}\left(y_{t}, y_{s}\right)$ and $\operatorname{cov}\left(x_{t}, y_{s}\right)$. With these definitions we obtain from (B6)-(B8):
(B10) $\Delta_{i j} \operatorname{cov}\left(x_{t}, x_{3}\right)=K\left[(i+j) \sigma_{\omega_{1} \omega_{2}}+(i s+j t-\mathrm{ij}) \sigma_{\omega_{2} \omega_{2}}+\mathrm{b}^{2}\left[(\mathrm{i}+\mathrm{j}) \sigma_{\lambda_{1} \lambda_{2}}+(\mathrm{is}+\mathrm{j} t-\mathrm{ij}) \sigma_{\lambda_{2} \lambda_{2}}\right]\right]$

$$
+\left(\delta_{t z}-\delta_{t-i,-j-j}\right) \sigma_{z e},
$$

(B11) $\Delta_{i j} \operatorname{cov}\left(\mathrm{y}_{\mathrm{i}}, \mathrm{y}_{8}\right)=\mathrm{K}\left[\mathrm{r}^{2}\left[(\mathrm{i}+\mathrm{j}) \sigma_{\omega_{1} \omega_{2}}+(\mathrm{is}+\mathrm{jt}-\mathrm{ij}) \sigma_{\omega_{2} \omega_{2}}\right]+(1+\mathrm{b})^{2}\left[(\mathrm{i}+\mathrm{j}) \sigma_{\lambda_{1} \lambda_{2}}+(\mathrm{is}+\mathrm{jt}-\mathrm{ij}) \sigma_{\lambda_{2} \lambda_{2}}\right]\right]$

$$
+\left(\delta_{t-}-\delta_{t-i,-j-j}\right) \sigma_{\varphi \varphi},
$$

(B12) $\Delta_{i j} \operatorname{cov}\left(x_{1}, y_{2}\right)=K\left[r\left[(i+j) \sigma_{\omega_{1} \omega_{2}}+(i s+j t-i j) \sigma_{\omega_{2} \omega_{2}}\right]+(1+b) b\left[(i+j) \sigma_{\lambda_{1} \lambda_{2}}+(i s+j t-i j) \sigma_{\lambda_{2} \lambda_{2}}\right]\right]$

$$
+\left(\delta_{t}-\delta_{t-i, i_{-}-j}\right) \sigma_{\varepsilon \varphi}
$$

For notational convenience we define, by the first equation in each of the following expressions
(B13) $D_{x x}=\Delta_{1,-1} \operatorname{cov}\left(x_{t}, x_{1}\right)=K\left[\sigma_{\omega_{2} \omega_{2}}+b^{2} \sigma_{\lambda_{2} \lambda_{2}}\right]+\sigma_{\varepsilon \varepsilon}$,
(B14) $D_{y y}=\Delta_{1,-1} \operatorname{cov}\left(y_{t}, y_{\mathfrak{z}}\right)=K\left[r^{2} \sigma_{\omega_{2} \omega_{2}}+(1+b)^{2} \sigma_{\lambda_{2} \lambda_{2}}\right]+\sigma_{\varphi \varphi}$,
(B15) $\mathrm{D}_{\mathrm{xy}}=\Delta_{1,-1} \operatorname{cov}\left(\mathrm{X}_{\mathrm{t}} \mathrm{y}_{\mathrm{l}}\right)=\mathrm{K}\left[\mathrm{ro}{\omega_{2} \omega_{2}}+(1+\mathrm{b}) \mathrm{b} \sigma_{\lambda_{2} \lambda_{2}}\right]+\sigma_{e \varphi}$,
(B16) $E_{x x}=\Delta_{11} \operatorname{cov}\left(x_{t} x_{y}\right)=K\left[2 \sigma_{\omega_{1} \omega_{2}}+(s+t-1) \sigma_{\omega_{2} \omega_{2}}+b^{2}\left[2 \sigma_{\lambda_{1} \lambda_{2}}+(s+t-1) \sigma_{\lambda_{2} \lambda_{2}}\right]\right]$,
(B17) $\mathrm{E}_{\mathrm{yy}}=\Delta_{11} \operatorname{cov}\left(\mathrm{y}_{\mathrm{t}} \mathrm{y}_{\mathrm{p}}\right)=\mathrm{K}\left[\mathrm{r}^{2}\left[2 \sigma_{\omega_{1} \omega_{2}}+\left(\mathrm{s}^{\dot{s}}+\mathrm{t}-1\right) \sigma_{\omega_{2} \omega_{2}}\right]+(1+\mathrm{b})^{2}\left[2 \sigma_{\lambda_{1} \lambda_{2}}+(\mathrm{s}+\mathrm{t}-1) \sigma_{\lambda_{2} \lambda_{2}}\right]\right]$,
(B18) $\mathrm{E}_{\mathrm{xy}}=\Delta_{11} \operatorname{cov}\left(\mathrm{x}_{\mathrm{t}} \mathrm{y}_{\mathrm{g}}\right)=\mathrm{K}\left[\mathrm{r}\left[2 \sigma_{\omega_{1} \omega_{2}}+(\mathbf{s}+\mathrm{t}-1) \mathrm{\sigma}_{\omega_{2} \omega_{2}}\right]+(1+\mathrm{b}) \mathrm{b}\left[2 \sigma_{\lambda_{1} \lambda_{2}}+(\mathbf{s}+\mathrm{t}-1) \sigma_{\lambda_{2} \lambda_{2}}\right]\right]$.

## B.4. General 2. order differences of $\mathbf{2}$. order moments

We define, for all possible combinations of $\mathrm{k}, \mathrm{l}, \mathrm{m}, \mathrm{n}, \mathrm{i}, \mathrm{j}, \mathrm{t}$, and s , the following general 2. order differences of 2 . order moments:
 and similarly for $\operatorname{cov}\left(\mathrm{y}_{\mathrm{t}}, \mathrm{y}_{\mathrm{s}}\right)$ and $\operatorname{cov}\left(\mathrm{x}_{\mathrm{t}}, \mathrm{y}_{\mathrm{s}}\right.$ ). From (B10)-(B12) we then obtain

 where

$$
\begin{aligned}
& \mathrm{K}_{1}=\mathrm{i}+\mathrm{j}-\mathrm{m}-\mathrm{n}, \\
& \mathrm{~K}_{2}=(\mathrm{i}-\mathrm{m}) \mathrm{s}+(\mathrm{j}-\mathrm{n}) \mathrm{t}-\mathrm{ij}+\mathrm{ml}+\mathrm{kn}+\mathrm{mn}, \\
& \mathrm{M}=\delta_{\mathrm{t}, \mathrm{~s}}-\delta_{\mathrm{t}-\mathrm{i}, \mathrm{~s}-\mathrm{j}}-\delta_{\mathrm{t}-\mathrm{k}, \mathrm{~s}-1}+\delta_{\mathrm{t}-\mathrm{k}-\mathrm{m}, \mathrm{~s}-\mathrm{l}-\mathrm{n}} .
\end{aligned}
$$

Note that M can take the following values: $-2,-1,0,1,2$. For the purpose of generating some of the identification results we define
(B23) $\mathcal{F}=\left\{(t, s, i, j, k, 1, m, n) \mid \mathrm{K}_{1}=0, \mathrm{~K}_{2} \neq 0\right\}$,
(B24) $\mathcal{G}=\left\{(\mathrm{t}, \mathrm{s}, \mathrm{i}, \mathrm{j}, \mathrm{k}, \mathrm{l}, \mathrm{m}, \mathrm{n}) \mid \mathrm{K}_{1} \neq 0, \mathrm{~K}_{2}=0\right\}$.
These sets are non-empty: all elements satisfying $\mathrm{i}=\mathrm{m}, \mathrm{j}=\mathrm{n}$, and $\mathrm{il}+\mathrm{kj} \neq 0$ constitute a subset of $\mathcal{F}$; an example of an element in $\mathcal{G}$ is $\mathrm{t}=4, \mathrm{~s}=3, \mathrm{i}=2, \mathrm{j}=-1, \mathrm{k}=1=\mathrm{m}=\mathrm{n}=1$. From (B20)-(B23) it then follows:

$$
\begin{equation*}
F_{x x}=\frac{\Delta_{\mathrm{k} l \mathrm{~mm}} \Delta_{\mathrm{y}} \operatorname{cov}\left(\mathrm{X}_{1}, \mathrm{x}_{\mathrm{p}}\right)}{\mathrm{K}_{2}}=K\left(\sigma_{\omega_{2} \omega_{2}}+b^{2} \sigma_{\lambda_{2} \lambda_{2}}\right), \tag{B25}
\end{equation*}
$$

(B26)

$$
F_{y y}=\frac{\Delta_{k i m n} \Delta_{i y} \operatorname{cov}\left(y_{t}, y_{p}\right)}{K_{2}}=K\left[r^{2} \sigma_{\omega_{2} \omega_{2}}+(1+b)^{2} \sigma_{\lambda_{2} \lambda_{2}}\right],
$$

(B27)
where the Fs are defined by the first equation in these formulas.
Similarly, it follows from (B20)-(B22) and (B24):

$$
\begin{equation*}
G_{x x}=\frac{\Delta_{\mathbf{k} \operatorname{man}} \Delta_{i j} \operatorname{cov}\left(x_{1}, x_{\mathbf{v}}\right)}{K_{1}}=K\left[\sigma_{\omega_{1} \omega_{2}}+b^{2} \sigma_{\lambda_{1} \lambda_{2}}\right], \tag{B28}
\end{equation*}
$$

(B29) $G_{y y}=\frac{\Delta_{\mathrm{k} \operatorname{ldn}} \Delta_{i j} \operatorname{cov}\left(y_{t}, y_{z}\right)}{K_{1}}=K\left[r^{2} \sigma_{\omega_{1} \omega_{2}}+(1+b)^{2} \sigma_{\lambda_{1} \lambda_{2}}\right]$,
(B30) $G_{x y}=\frac{\Delta_{\mathbf{l d m a}} \Delta_{i j} \operatorname{cov}\left(x_{1}, y_{8}\right)}{K_{1}}=K\left[r \sigma_{\omega_{1} \omega_{2}}+(1+b) b \sigma_{\lambda_{1} \lambda_{2}}\right]$.

We note that the Ds, Es, Fs, and Gs are observables. Viewed as sample statistics these expressions will depend on $k, l, m, n, i, j, t$, and $s$, (the Ds and Es only on $t$ and $s$ ), but viewed as population parameters they will, according to our model, be independent of these values. (In fact, any weighted average of any possible set of $\Delta_{\mathrm{klmn}} \Delta_{\mathrm{ij}} \operatorname{cov}\left(\mathrm{x}_{\mathrm{t}}, \mathrm{x}_{\mathrm{s}}\right) / \mathrm{K}_{2}$ will be a consistent estimate of the population parameter $\mathrm{F}_{\mathrm{xx}}$, and similarly for $F_{y y}$ and $F_{x y}$, and for all the Ds, Es, and Gs.) The equations defining the Ds, Es, Fs, and Gs can be used for various tests. In this appendix they are used only to study identification.

## B.5. Identification of $\sigma_{\varepsilon \varepsilon}, \sigma_{\varphi \varphi}$, and $\sigma_{\varepsilon \varphi}$ for all models

From (B25)-(B27) and (B13)-(B15) we obtain
(B31) $\quad \sigma_{z z}=D_{x y}-F_{x x}$,
(B32) $\sigma_{\varphi \varphi}=D_{y y}-F_{y y}$,
(B33) $\quad \sigma_{z \varphi}=D_{x y}-F_{x y}$,
which identify the variances and covariances of the errors of measurement for M1W3L3 and for all its submodels. Note that the parameter $\sigma_{\varepsilon \varphi}$ is not involved in the identification of $\sigma_{\varepsilon \varepsilon}$ and $\sigma_{\varphi \varphi}$, and neither in the identification of the other parameters below. Our identification results are thus equally valid for M0W3L3, where $\sigma_{\varepsilon \varphi}=0$, and for M1W3L3, where this covariance is not restricted.

## B.6. Identification of $\mathbf{r}$ and $b$

## Relationship between band r

From (B7) and (B8) we obtain, for $t \neq s$
(B37) $\operatorname{cov}\left(y_{t}, y_{8}\right)-\operatorname{rcov}\left(x_{r}, y_{8}\right)=K(1+b) d\left[\sigma_{\lambda_{1} \lambda_{1}}+(t+s) \sigma_{\lambda_{1} \lambda_{2}}+t s \sigma_{\lambda_{2} \lambda_{2}}\right]$.
From (B8) and (B6) we obtain, also for $t \neq s$
(B38)

$$
\operatorname{cov}\left(x_{1}, y_{2}\right)-\operatorname{rcov}\left(x_{1}, x_{2}\right)=\operatorname{Kbd}\left[\sigma_{\lambda_{1} \lambda_{1}}+(t+s) \sigma_{\lambda_{1} \lambda_{2}}+t s \sigma_{\lambda_{2} \lambda_{2}}\right] .
$$

Assuming $\sigma_{\lambda 1 \lambda 1} \neq 0$, (which for $t \neq s$ secures that the square bracket in (B38) is not zero), we divide (B37) by (B38) to obtain

$$
\begin{equation*}
b=\frac{\operatorname{cov}\left(x_{1}, y_{8}\right)-r \operatorname{cov}\left(x_{1}, x_{8}\right)}{\operatorname{cov}\left(y_{\imath}, y_{\nabla}\right)-\operatorname{cov}\left(x_{1}, y_{8}\right)+r\left(\operatorname{cov}\left(x_{t}, x_{8}\right)-\operatorname{cov}\left(x_{1}, y_{\nabla}\right)\right)} \tag{B39}
\end{equation*}
$$

which identifies $b$ in all models where $r$ already has been identified, with the exception of the four submodels in W3L0 (when $\sigma_{\lambda 1 \lambda 1}=0$, and the denominator in (B39) also is zero). In section B. 7 below it is demonstrated that b is not identifiable in W3L0.

Solving (B39) with respect to r gives, if the denominator is different from zero,

$$
\begin{equation*}
r=\frac{(1+b) \operatorname{cov}\left(x_{p}, y_{p}\right)-b \operatorname{cov}\left(y_{p}, y_{p}\right)}{(1+b) \operatorname{cov}\left(x_{p}, x_{p}\right)-b \operatorname{cov}\left(x_{p}, y_{p}\right)} \tag{B40}
\end{equation*}
$$

which identifies $r$ if $b$ already has been identified. In model WOL3 the denominator (and also the numerator) is zero, and (B40) cannot be used to identify $r$ in this case (including four submodels). It can be demonstrated, analogously to the proof in section B. 7 of the non-identifiabilify of $b$ in W3L0, that $r$ cannot be identified in W0L3.

We will now first identify $r$ in those models where this is easily done by help of Fs and Gs. Equation (B39) can in these cases be used to identify b. Similarly, we will identify $b$ in some of the remaining models, and use (B40) to identify $r$. Finally, identification of these two parameters in two of the models will be obtained by a more comprehensive analysis. The number of the equations used to identify each parameter in the various models are given in Table B1. The first four rows of this table show the results for the four submodels of $W 3{ }^{*} L 3$, the next four

Table B1

[^9]those of $W 2^{*} \mathrm{~L} 3$, etc.

W3 ${ }^{*}$ L2 ${ }^{*}$
For model $W 3^{*} \mathrm{~L} 2^{*}$ identification of $r$ is obtained by dividing (B30) by (B29), which gives
(B41) $r=\frac{G_{x y}}{G_{z i}}$.
$W 3^{*} L 1^{*}, W 3^{*} L 0^{*}, W 2^{*} L 1^{*}$, and $W 2^{*} L 0^{*}$
For these models identification of $r$ is obtained by dividing (B27) by (B25), which gives
(B42) $\quad r=\frac{F_{x y}}{F_{x x}}$.

## $W 1^{*} L 1^{*}, W 1^{*} L 0^{*}, W 1^{*} L 1^{*}$, and $W 1^{*} L 0^{*}$

For model W1L1 (including the four above mentioned submodels) the differences of the 2 . order moments, ( B 10 )-(B12), and the differences of these differences, (B20)-(B22) are zero, and one is left with the simple covariances for identification. (B6)-(B8) are now simplified to
(B43) $\operatorname{cov}\left(x_{1}, x_{\imath}\right)=K\left[\sigma_{\omega_{1} \omega_{1}}+b^{2} \sigma_{\lambda_{1} \lambda_{1}}\right]+\delta_{z E} \sigma_{z \varepsilon}$,
(B44) $\operatorname{cov}\left(y_{\imath}, y_{\ell}\right)=K\left[r^{2} \sigma_{\omega_{1} \omega_{1}}+(1+b)^{2} \sigma_{\lambda_{1} \lambda_{1}}\right]+\delta_{t} \sigma_{\phi \phi}$,
(B45) $\operatorname{cov}\left(x_{1}, y_{p}\right)=K\left[r \sigma_{\omega_{1} \omega_{1}}+(1+b) b \sigma_{\lambda_{1} \lambda_{1}}\right]+\delta_{t 3} \sigma_{\phi \phi} \cdot$
For submodel $W 1^{*} L 1^{*}$, for which $\sigma_{\omega 1 \omega 1} \neq 0$ and $\sigma_{\lambda 1 \lambda 1} \neq 0$, we thus, for $\mathrm{t} \neq \mathrm{s}$, have only three equations, independent of time, in the four parameters $b, r, \sigma_{\omega 1 \omega 1}$, and $\sigma_{\lambda 1 \lambda 1}$. They cannot all be identified without further information. If, for instance, $\mathbf{r}$ is given a fixed value, the remaining parameters are easily identified, cf section 5.7 .

For submodel $\mathrm{W} 1^{*} \mathrm{~L} 0^{*}$ identification is obtained by dividing, for $\mathrm{t} \neq \mathrm{s}$, (B45) by (B43), which in this case, when $\sigma_{\lambda 1 \lambda 1}=0$, gives
(B46) $r=\frac{\operatorname{cov}\left(x_{1}, y_{\theta}\right)}{\operatorname{cov}\left(x_{1}, x_{8}\right)}$.
For submodel $W 0^{*} L 0^{*}$, $r$ cannot be identified even if $b$ is given a fixed value, and vice versa.

## $W 2^{*} L 3^{*}$

Identification of b in model $\mathrm{W} 2^{*} \mathrm{~L} 3^{*}$ is obtained by dividing (B28) by (B30) which gives
(B47) $\quad b=\frac{G_{x x}}{G_{x y}-G_{x x}}$.
$W 1^{*} L 3^{*}, W 1^{*} L 2^{*}, W 0^{*} L 3^{*}$, and $W 0^{*} L 2^{*}$
Identification of $b$ in these four models is obtained by dividing (B25) by (B27), which gives, after some ordering
(B48) $\quad b=\frac{F_{x x}}{F_{x y}-F_{x y}}$.

W0 ${ }^{*} L 1^{*}$
Identification of b in $\mathrm{W} 0^{*} \mathrm{~L} 1^{*}$ is obtained by dividing (B43) by (B45), which gives (B49) $\quad b=\frac{\operatorname{cov}\left(x_{t}, x_{8}\right)}{\operatorname{cov}\left(x_{t}, y_{3}\right)-\operatorname{cov}\left(x_{t}, x_{3}\right)}$.

## $W 3^{*} L 3^{*}$

Multiplying (B25) by r, and subtracting (B27) from the resulting equation gives (B50) $\quad \mathrm{F}_{\mathrm{xx}} \mathrm{I}-\mathrm{F}_{\mathrm{xy}}=\mathrm{K}\left[\mathrm{rb}^{2}-(1+\mathrm{b}) \mathrm{b}\right] \sigma_{\lambda_{2} \lambda_{2}}=-\mathrm{Kbd} \sigma_{\lambda_{2} \lambda_{2}}$.

Multiplying (B27) by r, and subtracting the resulting equation from (B26) gives
(B51)

$$
\mathrm{F}_{\mathrm{yy}}-\mathrm{F}_{\mathrm{xy}} \mathrm{I}=\mathrm{K}\left[(1+\mathrm{b})^{2}-\mathrm{r}(1+\mathrm{b}) \mathrm{b}\right] \sigma_{\lambda_{\lambda_{2}} \lambda_{2}}=\mathrm{K}(1+\mathrm{b}) \mathrm{d} \sigma_{\lambda_{2} \lambda_{2}} .
$$

Assuming $\sigma_{\lambda 2 \lambda 2} \neq 0$ and $\mathrm{b} \neq-1$ (identification when $\mathrm{b}=-1$ is demonstrated below), we divide (B50) by (B51) to obtain
(B52) $\frac{F_{x x} r-F_{x y}}{F_{y y}-F_{x y} T}=-\frac{b}{(1+b)}$.
Multiplying, for $\mathrm{i}=\mathrm{j}=1$, (B16) by r and subtracting (B18) from the resulting equation gives:
(B53) $\mathrm{rE}_{\mathrm{xx}}-\mathrm{E}_{\mathrm{xy}}=-\operatorname{Kbd}\left[2 \sigma_{\lambda_{1} \lambda_{2}}+(\mathrm{t}+\mathrm{s}-1) \sigma_{\lambda_{2} \lambda_{2}}\right]$.
Multiplying, also here for $i=j=1$, (B16) by $r$, and subtracting the resulting equation from (B17) gives
(B54) $\mathrm{E}_{\mathrm{yy}}-\mathrm{TE} \mathrm{E}_{\mathrm{xy}}=\mathrm{K}(1+\mathrm{b}) d\left[2 \sigma_{\lambda_{1} \lambda_{2}}+(\mathrm{t}+\mathrm{s}-1) \sigma_{\lambda_{2} \lambda_{2}}\right]$.
Observing that, for at least some $t$ and $s, 2 \sigma_{\lambda 1 \lambda 2}+(t+s-1) \sigma_{\lambda 2 \lambda 2} \neq 0$, we divide (B53) by (B54) to obtain
(B55) $\frac{\mathrm{rE}_{\mathrm{xx}}-\mathrm{E}_{\mathrm{xy}}}{\mathrm{E}_{\mathrm{yy}}-\mathrm{rE}_{x y}}=-\frac{\mathrm{b}}{1+\mathrm{b}}$.
From equations (B52) and (B55) then follows
(B50) $r^{2}\left[F_{x y} E_{x y}-F_{x y} E_{x y}\right]+r\left[F_{x x} E_{y y}-F_{y y} E_{x y}\right]+\left[F_{y y} E_{x y}-F_{x y} E_{y y}\right]=0$.
This equation cannot be used to identify r if the first two square brackets are zero. Inserting from equations (B16)-(B18) and (B25)-(B27) into (B56) gives
(B57) $\quad \mathbf{r}^{2}\left[2 K^{2} b d \sigma_{\lambda_{2} \lambda_{2}} \sigma_{\omega_{1} \omega_{2}}\right]+\left[2 K^{2}\left(r^{2} b^{2}-(1+b)^{2}\right) \sigma_{\lambda_{2} \lambda_{2}} \sigma_{\omega_{1} \omega_{2}}\right]+\left[2 K^{2} r(1+b) d \sigma_{\lambda_{2} \lambda_{2}} \sigma_{\omega_{1} \omega_{2}}\right]=0$, where the three square brackets are equal to those of (B56), respectively. Equation (B57) shows that all three square brackets in (B56) are equal to zero except for $\mathrm{W} 3^{*} \mathrm{~L} 2^{*}$ and $\mathrm{W} 3^{*} \mathrm{~L} 3^{*}$. Identification of b and r in the former model is already proved. For the latter model, (B56) is a second order equation in $r$ that in general has two different solutions. This problem of two roots is discussed in Sections 3 and B.10, where additional assumptions are introduced in order to choose between the two. If r is identified by this procedure, identification of b follows from (B39).
$W 2^{*} L 2^{*}$
Observing that we in model $\mathrm{W} 2^{*} \mathrm{~L} 2^{*}$ have $\sigma_{\omega 1 \omega 2}=\sigma_{\lambda 1 \lambda 2}=0$, multiplication of (B6) by $r$ and subtraction of (B8) from the resulting equation gives, for $t \neq s$
(B58) $\operatorname{rcov}\left(x_{r} x_{p}\right)-\operatorname{cov}\left(x_{r}, y_{p}\right)=-\operatorname{Kbd}\left(\sigma_{\lambda_{1} \lambda_{1}}+\operatorname{ts} \sigma_{\lambda_{2} \lambda_{2}}\right)$.
Multiplying (B8) by $r$ and subtracting the resulting equation from (B7) gives
(B59) $\quad \operatorname{cov}\left(y_{t}, y_{8}\right)-\operatorname{rov}\left(x_{t}, y_{2}\right)=K(1+b) d\left(\sigma_{\lambda_{1} \lambda_{1}}+\operatorname{ts} \sigma_{\lambda_{2} \lambda_{2}}\right)$.
Dividing the former by the latter gives
(B60) $\frac{\operatorname{rcov}\left(x_{1}, x_{8}\right)-\operatorname{cov}\left(x_{1}, y_{8}\right)}{\operatorname{cov}\left(y_{t}, y_{8}\right)-\operatorname{rov}\left(x_{1}, y_{8}\right)}=-\frac{b}{1+b}$.
From (B52) (which is valid also for the present model) and (B60) follows
(B61) $\quad r^{2}\left[F_{x y} \operatorname{cov}\left(x_{t}, x_{8}\right)-F_{x x} \operatorname{cov}\left(x_{t}, y_{g}\right)\right]$

$$
\begin{aligned}
& +r\left[F_{x x} \operatorname{cov}\left(y_{t}, y_{y}\right)-F_{y y} \operatorname{cov}\left(\left(x_{t}, x_{p}\right)\right]\right. \\
& +\left[F_{y y} \operatorname{cov}\left(x_{p}, y_{p}\right)-F_{x y} \operatorname{cov}\left(y_{t}, y_{z}\right)\right]=0 .
\end{aligned}
$$

Here, too, identification of $r$ is not possible if the square brackets are equal to zero. Inserting (B6)-(B8) (for $\mathrm{t} \neq \mathrm{s}$, and $\sigma_{\omega 1 \omega 2}=\sigma_{\lambda 1 \lambda 2}=0$ ) and (B25)-(B27) into (B61) gives (B62) $\mathrm{r}^{2}\left[-\mathrm{K}^{2} \mathrm{bd}\left(\sigma_{\lambda_{1} \lambda_{1}} \sigma_{\omega_{2} \omega_{2}}-\sigma_{\lambda_{2} \lambda_{2}} \sigma_{\omega_{1} \omega_{1}}\right)\right]$

$$
\begin{aligned}
& +\mathrm{r}\left[\mathrm{~K}^{2}\left(\mathrm{~b}^{2} \mathrm{r}^{2}-(1+\mathrm{b})^{2}\right)\left(\sigma_{\lambda_{1} \lambda_{1}} \sigma_{\omega_{2} \omega_{2}}-\sigma_{\lambda_{2} \lambda_{2}} \sigma_{\omega_{1} \omega_{1}}\right)\right] \\
& +\left[\mathrm{K}^{2} \mathrm{r}(1+\mathrm{b}) \mathrm{d}\left(\sigma_{\lambda_{1} \lambda_{1}} \sigma_{\omega_{2} \omega_{2}}-\sigma_{\omega_{1} \omega_{1}} \sigma_{\lambda_{2} \lambda_{2}}\right)\right]=0
\end{aligned}
$$

The three brackets in (B62), corresponding to those of (B61), are in general not zero, and equation (B61) can be used to identify $r$ and $b$ by the same procedure as for W3 ${ }^{*} \mathrm{~L} 3^{*}$.

Identification of $r$ when $b=-1$
Discussing identification of $\mathrm{W} 3^{*} \mathrm{~L} 3^{*}$ and $\mathrm{W} 2^{*} \mathrm{~L} 2^{*}$ we used the assumption $\mathrm{b} \neq-1$. When $b=-1$, it follows from (B40) that
(B63) $r=\frac{\operatorname{cov}\left(y_{t}, y_{p}\right)}{\operatorname{cov}\left(x_{t}, y_{p}\right)}$,
which identifies $r$. Identification of the remaining parameters does not depend on the value of $b, c f$ section B.8.

## B.7. Proof of non-identifiability of $b$ in W3L0

If $\sigma_{\lambda 1 \lambda 1}=0$, which then gives model W3L0, full identification of all parameters are not possible. Additional information, for instance a fixed value of one of the parameters, is needed to obtain complete identification.

Rewriting (B6)-(B8)
(B69) $\operatorname{cov}\left(\mathrm{X}_{1}, \mathrm{x}_{\varepsilon}\right)-\delta_{t z} \sigma_{\varepsilon \varepsilon}=\mathrm{K}\left[\sigma_{\omega_{1} \omega_{1}}+(t+s) \sigma_{\omega_{1} \omega_{2}}+t s \sigma_{\omega_{2} \omega_{2}}\right]$,
(B70) $\operatorname{cov}\left(\mathrm{y}_{\mathrm{t}}, \mathrm{y}_{\boldsymbol{\gamma}}\right)-\delta_{\mathbf{t}} \sigma_{\phi \phi}=\operatorname{Kr}^{2}\left[\sigma_{\omega_{1} \omega_{1}}+(t+s) \sigma_{\omega_{1} \omega_{2}}+t s \sigma_{\omega_{2} \omega_{2}}\right]$,
(B71) $\operatorname{cov}\left(X_{1}, y_{2}\right)-\delta_{t s} \sigma_{z \phi}=\operatorname{Kr}\left[\sigma_{\omega_{1} \omega_{1}}+(t+s) \sigma_{\omega_{1} \omega_{2}}+t s \sigma_{\omega_{2} \omega_{2}}\right]$,
we remark that $\sigma_{\varepsilon \varepsilon}, \sigma_{\varphi \varphi}, \sigma_{\varepsilon \varphi}$, and r are already identified in $\mathrm{W} 3^{*} \mathrm{~L} 0^{*}, \mathrm{~W} 2^{*} \mathrm{~L} 0^{*}$, and $\mathrm{W} 1^{*} \mathrm{~L} 0^{*}$, cf Table B1. (In submodel $\mathrm{W} 0^{*} \mathrm{~L} 0^{*} \mathrm{r}$ cannot be identified, and the proof below is irrelevant.)

Assume that $\hat{b}, \hat{\sigma}_{\omega 1 \omega 1}, \hat{\sigma}_{\omega 2 \omega 2}$, and $\hat{\sigma}_{\omega 1 \omega 2}$ satisfy (B69)-(B71) for given values of $\sigma_{\varepsilon \varepsilon}, \sigma_{\varphi \varphi} \cdot \sigma_{\varepsilon \varphi}$, and $r$. Then it can be shown that the same must be true for
 where $h$ is a positive scalar. For the above assertion to hold we must have $\mathbf{h K}\left(\mathbf{b}^{*}, \mathbf{r}\right)=\mathbf{K}(\hat{\mathrm{b}}, \mathbf{r})$, where

$$
K\left(b^{*}, r\right)=\left[\frac{1}{1+b^{*}-\mathrm{rb}^{*}}\right]^{2} \text {, and } K(\hat{b}, r)=\left[\frac{1}{1+\hat{b}-\mathrm{r} b}\right]^{2}
$$

Inserting for $\mathrm{b}^{*}$ we obtain

$$
\begin{aligned}
h K\left(b^{*}, r\right)= & h\left[\frac{1}{1+b^{*}-r b^{*}}\right]^{2}=\left[\frac{\sqrt{h}}{1+\frac{\sqrt{h}(1+b-b r)-1}{1-r}-r\left(\frac{\sqrt{h}(1+b-b r)-1}{1-r}\right)}\right]^{2}= \\
& {\left[\frac{\sqrt{h}}{1+\frac{(1-r)[\sqrt{h}(1+b-6 r)-1]}{1-r}}\right]^{2}=\left[\frac{1}{1+6-6 r}\right]^{2}=K(6, r) }
\end{aligned}
$$

This means that $\mathrm{b}, \sigma_{\omega 1 \omega 1}, \sigma_{\omega 2 \omega 2}$, and $\sigma_{\omega 1 \omega 2}$ cannot be identified. If, for instance, b is given a fixed value, the three remaining parameters can be obtained from (B69)-(B71).

A similar proof, not given in this paper, will show that $\mathbf{r}$ is not identifiable in W0L3.

## B.8. Identification of $\sigma_{\omega 1 \omega 1}, \sigma_{\lambda 1 \lambda 1}, \sigma_{\omega 2 \omega 2}, \sigma_{\lambda 2 \lambda 2}, \sigma_{\omega 1 \omega 2}$, and $\sigma_{\lambda 1 \lambda 2}$

For the submodels where $b$ and $r$ have been identified, the parameters $\sigma_{\omega 2 \omega 2}$ and $\sigma_{\lambda 2 \lambda 2}$ are identified by (B25) and (B26), which are two linear equations in these parameters. Thereafter we identify the parameters $\sigma_{\omega 1 \omega 2}$ and $\sigma_{\lambda 1 \lambda 2}$ by (B28) and (B29), and finally we determine $\sigma_{\omega 1 \omega 1}$ and $\sigma_{\lambda 1 \lambda 1}$ from (B6) and (B8).

## B.9. Observational equivalence between $\mathrm{Wi}^{*} \mathrm{Lj}^{\mathbf{*}}$ and $\mathrm{Wj}^{\mathbf{*}} \mathrm{Li}^{*}$

The demonstration of identification above needs a qualification. The models $\mathrm{Wi}^{*} \mathrm{Lj}^{*}$ and $\mathrm{Wj}^{*} \mathrm{Li}^{*}$ for $\mathrm{i} \neq \mathrm{j}$ and $\mathrm{i}, \mathrm{j}=0,1,2,3$ can be shown to be pairwise observationally equivalent. Here we restrict ourselves to prove this proposition for the most general pair of models, i.e. $\mathrm{W} 2^{*} \mathrm{~L} 3^{*}$ and $\mathrm{W} 3^{*} \mathrm{~L} 2^{*}$. The proof for other pairs is analogous, but somewhat simpler.

Let $b^{\prime}, r^{\prime}, d^{\prime}, \sigma_{\omega 1 \omega 1^{\prime}}, \sigma_{\omega 2 \omega 2^{\prime}}, \sigma_{\lambda i \lambda 1^{\prime}}, \sigma_{\lambda 2 \lambda 2^{\prime}}, \sigma_{\varepsilon \varepsilon}{ }^{\prime}, \sigma_{\varphi \varphi^{\prime}}$, and $\sigma_{\varepsilon \varphi}{ }^{\prime}$ be the values of $\mathrm{b}, \mathrm{r}, \mathrm{d}, \sigma_{\omega 1 \omega 1}, \sigma_{\omega 2 \omega 2}, \sigma_{\lambda 1 \lambda 1}, \sigma_{\lambda 2 \lambda 2}, \sigma_{\varepsilon \varepsilon}, \sigma_{\varphi \varphi}$, and $\sigma_{\varepsilon \varphi}$, respectively, in W3L2, and $\mathrm{b} ", \mathrm{r} ", \mathrm{~d} ", \sigma_{\omega 1 \omega 1} ", \sigma_{\omega 2 \omega 2} ", \sigma_{\lambda 1 \lambda 1} ", \sigma_{\lambda 2 \lambda 2} ", \sigma_{\varepsilon \varepsilon} ", \sigma_{\varphi \varphi} "$, and $\sigma_{\varepsilon \varphi} "$ the values of the same parameters in W2L3. For W3L2 to be observationally equivalent to W2L3 they have to imply the same theoretical moments of the observable variables. This means that the following identities must hold for all possible combinations of $t$ and s. (cf (B6)-(B8)):
(B72) $\left[K\left(b^{\prime}, \mathbf{r}\right)\left[\sigma_{\omega_{1} \omega_{1}}^{\prime}+b^{2} \sigma_{\lambda_{1} \lambda_{1}}^{\prime}\right]-K\left(b^{\prime \prime}{ }_{1} \mathbf{r}^{\prime \prime}\right)\left[\sigma_{\omega_{1} \omega_{1}}^{\prime \prime}+b^{\prime 2} \sigma_{\lambda_{1} \lambda_{1} 1}^{\prime \prime}\right]\right.$

$$
\begin{aligned}
& +\left[\mathbf{K}\left(\mathbf{b}^{\prime}, \mathbf{r}\right) \sigma_{\omega_{1} \omega_{2}}^{\prime}-K\left(b^{\prime \prime}, r^{\prime \prime}\right) b^{\prime 2} \sigma_{\lambda_{1} \lambda_{2}}^{\prime \prime}\right](t+s) \\
& +\left[K ( b ^ { \prime } , r ) \left[\sigma_{\omega_{2} \omega_{2}}^{\prime}+b^{\prime 2} \sigma_{\lambda_{2} \lambda_{2}}^{\prime}-K\left(b^{\prime \prime}, r^{\prime \prime}\right)\left[\sigma_{\omega_{2} \omega_{2}}^{\prime \prime}+b^{\prime 2} \sigma_{\lambda_{2} \lambda_{2}}^{\prime \prime}\right] t s+\delta_{t z}\left[\sigma_{z \varepsilon}^{\prime}-\sigma_{z \varepsilon}^{\prime \prime}\right]=0,\right.\right.
\end{aligned}
$$

(B73) $\left[K\left(b^{\prime},_{1}\right)\left[r^{2} \sigma_{\omega_{1} \omega_{1}}^{\prime}+\left(1+b^{\prime}\right)^{2} \sigma_{\lambda_{1} \lambda_{1}}^{\prime}\right]-K\left(b^{\prime \prime} \mathbf{r}^{\prime \prime}\right)\left[\mathbf{r}^{\prime 2} \sigma_{\omega_{1} \omega_{1}}^{\prime \prime}+\left(1+b^{\prime \prime}\right)^{2} \sigma_{\lambda_{1} \lambda_{1}}^{\prime \prime}\right]\right]$

$$
\begin{aligned}
& +\left[K\left(b^{\prime}, \mathbf{r}\right) \mathbf{r}^{2} \sigma_{\omega_{1} \omega_{2}}^{\prime}-K\left(b^{\prime \prime}, \mathbf{r}^{\prime \prime}\right)\left(1+b^{\prime}\right)^{2} \sigma_{\lambda_{1} \lambda_{2}}^{\prime \prime}\right](t+s) \\
& +\left[K\left(b^{\prime}, \mathbf{r}^{\prime}\right)\left[\mathbf{r}^{2} \sigma_{\omega_{2} \omega_{2}}^{\prime}+\left(1+b^{\prime}\right)^{2} \sigma_{\lambda_{2} \lambda_{2}}^{\prime}\right]-K\left(b^{\prime \prime}, \mathbf{r}^{\prime \prime}\right)\left[\mathbf{r}^{\prime 2} \sigma_{\omega_{2} \omega_{2}}^{\prime \prime}+\left(1+b^{\prime \prime}\right)^{2} \sigma_{\lambda_{2} \lambda_{2}}^{\prime \prime}\right] t s\right. \\
& +\delta_{t \leq 1}\left[\sigma_{\varphi \varphi}^{\prime}-\sigma_{\varphi \varphi}^{\prime \prime}\right]=0,
\end{aligned}
$$

(B74) $\left[K\left(b^{\prime}, r\right)\left[r^{\prime} \sigma_{\omega_{1} \omega_{1}}^{\prime}+\left(1+b^{\prime}\right) b^{\prime} \sigma_{\lambda_{1} \lambda_{1}}^{\prime}\right]-K\left(b^{\prime \prime}, r^{\prime \prime}\right)\left[r^{\prime \prime} \sigma_{\omega_{1} \omega_{1}}^{\prime \prime}+\left(1+b^{\prime \prime}\right) b^{\prime \prime} \sigma_{\lambda_{1} \lambda_{1}}^{\prime \prime}\right]\right]$

$$
+\left[\mathbf{K}\left(\mathbf{b}^{\prime}, r^{\prime}\right) \mathbf{r}^{\prime} \boldsymbol{\sigma}_{\omega_{1} \omega_{2}}^{\prime}-\mathbf{K}\left(\mathbf{b}^{\prime \prime}{ }_{2} \mathbf{r}^{\prime \prime}\right)\left(1+\mathbf{b}^{\prime}\right) \mathbf{b}^{\prime \prime} \sigma_{\lambda_{1} \lambda_{2}}^{\prime \prime}\right](t+s)
$$

$$
+\left[\mathbf{K}\left(\mathbf{b}^{\prime}, \mathbf{r}\right)\left[\mathbf{r}^{\prime} \sigma_{\omega_{2} \omega_{2}}^{\prime}+\left(1+b^{\prime}\right) \mathbf{b}^{\prime} \sigma_{\lambda_{2} \lambda_{2}}^{\prime}\right]-\mathbf{K}\left(\mathbf{b}^{\prime \prime}, \mathbf{r}^{\prime \prime}\right)\left[\mathbf{r}^{\prime \prime} \sigma_{\omega_{2} \omega_{2}}^{\prime \prime}+\left(1+\mathbf{b}^{\prime \prime}\right) \mathbf{b}^{\prime \prime} \sigma_{\lambda_{2} \lambda_{2}}^{\prime \prime}\right] \operatorname{ts}\right.
$$

$$
+\delta_{t v}\left[\sigma_{z \varphi}^{\prime}-\sigma_{z \varphi}^{\prime \prime}\right]=0
$$

For (B72)-(B74) to hold as identities the following relations must apply:
(B75) $K\left(b^{\prime}, \mathbf{r}\right)\left[\sigma_{\omega_{1} \omega_{1}}^{\prime}+b^{2} \sigma_{\lambda_{1} \lambda_{1}}^{\prime}\right]=K\left(b^{\prime \prime}{ }^{\prime} \mathbf{I}\right)\left[\sigma_{\omega_{1} \omega_{1}}^{\prime \prime}+b^{\prime 2} \sigma_{\lambda_{1} \lambda_{1}}^{\prime \prime}\right]$,
(B76) $K\left(b^{\prime}, \mathbf{r}\right) \sigma_{\omega_{1} \omega_{2}}^{\prime}=K\left(b^{\prime \prime}{ }^{\prime \prime}\right) b^{\prime 2} \sigma_{\lambda_{1} \lambda_{2}}^{\prime \prime}$.
(B77) $K\left(b^{\prime}{ }_{r} r\right)\left[\sigma_{\omega_{2} \omega_{2}}^{\prime}+b^{2} \sigma_{\lambda_{2} \lambda_{2}}^{\prime}\right]=K\left(b^{\prime \prime}{ }^{\prime \prime}\right)\left[\sigma_{\omega_{2} \omega_{2}}^{\prime \prime}+b^{\prime 2} \sigma_{\lambda_{2} \lambda_{2}}^{\prime \prime}\right]$,
(B78) $\sigma_{z \varepsilon}^{\prime}=\sigma_{z z}^{\prime \prime}$,
(B79) $K\left(b^{\prime} \mathbf{r}^{\prime}\right)\left[\mathbf{r}^{2} \sigma_{\omega_{1} \omega_{1}}^{\prime}+\left(1+b^{\prime}\right)^{2} \sigma_{\lambda_{1} \lambda_{1}}^{\prime}\right]=K\left(b^{\prime \prime}, r^{\prime \prime}\right)\left[\mathbf{r}^{\prime 2} \sigma_{\omega_{1} \omega_{1}}^{\prime \prime}+\left(1+b^{\prime \prime}\right)^{2} \sigma_{\lambda_{1} \lambda_{1}}^{\prime \prime}\right]$,
(B80) $K\left(\mathbf{b}^{\prime}{ }^{\prime} r^{\gamma} \mathbf{r}^{\wedge} \sigma_{\omega_{1} \omega_{2}}^{\prime}=K\left(\mathbf{b}^{\prime \prime}, \mathbf{r}^{\prime \prime}\right)\left(1+\mathbf{b}^{\prime \prime}\right)^{2} \sigma_{\lambda_{1} \lambda_{2}}^{\prime \prime}\right.$,
(B81) $K\left(b^{\prime}{ }^{\prime} r^{\prime}\right)\left[\mathbf{r}^{2} \sigma_{\omega_{2} \omega_{2}}^{\prime}+(1+b)^{2} \sigma_{\lambda_{2} \lambda_{2}}^{\prime}\right]=K\left(b^{\prime \prime}{ }_{5} \mathbf{r}^{\prime \prime}\right)\left[\mathbf{r}^{\prime 2} \sigma_{\omega_{2} \omega_{2}}^{\prime \prime}+\left(1+b^{\prime \prime}\right)^{2} \sigma_{\lambda_{2} \lambda_{2}}^{\prime \prime}\right]$,
(B82) $\sigma_{\varphi \varphi}^{\prime}=\sigma_{\varphi \varphi}^{\prime \prime}$,
(B83) $K\left(b^{\prime}{ }_{5}{ }^{\prime}\right)\left[r^{\prime} \sigma_{\omega_{1} \omega_{1}}^{\prime}+\left(1+b^{\prime}\right) b^{\prime} \sigma_{\lambda_{1} \lambda_{1}}^{\prime}\right]=K\left(b^{\prime \prime}{ }_{5} \mathbf{r}^{\prime \prime}\right)\left[r^{\prime \prime} \sigma_{\omega_{1} \omega_{1}}^{\prime \prime}+\left(1+b^{\prime \prime}\right) b^{\prime \prime} \sigma_{\lambda_{1} \lambda_{1}}^{\prime \prime}\right]$,
(B84) $K\left(b^{\prime} r\right) r^{\prime} \sigma_{\omega_{1} \omega_{2}}^{\prime}=K\left(b^{\prime \prime} r^{\prime \prime}\right)\left(1+b^{\prime}\right) b^{\prime \prime} \sigma_{\lambda_{1} \lambda_{2}}^{\prime \prime}$.
(B85) $K\left(b^{\prime},^{\prime}\right)\left[\mathbf{r}^{\prime} \sigma_{\omega_{2} \omega_{2}}^{\prime}+\left(1+b^{\prime}\right) b^{\prime} \sigma_{\lambda_{2} \lambda_{2}}^{\prime}\right]=K\left(b^{\prime \prime},^{\prime \prime}\right)\left[\mathbf{r}^{\prime \prime} \sigma_{\omega_{2} \omega_{2}}^{\prime \prime}+\left(1+b^{\prime \prime}\right) b^{\prime \prime} \sigma_{\lambda_{2} \lambda_{2}}^{\prime \prime}\right]$,
(B86) $\sigma_{\varepsilon \varphi}^{\prime}=\sigma_{\varepsilon \varphi}^{\prime \prime}$.

From (B75)-(B86) it is now possible to solve for
$\sigma_{e \varepsilon}^{\prime \prime}, \sigma_{\varphi \varphi}^{\prime \prime}, \sigma_{e \varphi}^{\prime \prime}, \mathbf{b}^{\prime \prime}, \mathbf{r}^{\prime \prime}, \sigma_{\omega_{1} \omega_{1}}^{\prime \prime}, \sigma_{\omega_{2} \omega_{2}}^{\prime \prime}, \sigma_{\lambda_{1} \lambda_{1}}^{\prime \prime}, \sigma_{\lambda_{1} \lambda_{2}}^{\prime \prime}$, and $\sigma_{\lambda_{2} \lambda_{2}}^{\prime \prime}$ as functions of $\sigma_{\varepsilon \varepsilon}^{\prime}, \sigma_{\varphi \varphi}^{\prime}, \sigma_{e \varphi}^{\prime}, \mathbf{b}^{\prime}, \mathbf{r}^{\prime}, \sigma_{\omega_{1} \omega_{1}}^{\prime}, \sigma_{\omega_{1} \omega_{2}}^{\prime}, \sigma_{\omega_{2} \omega_{2}}^{\prime}, \sigma_{\lambda_{1} \lambda_{1}}^{\prime}$, and $\sigma_{\lambda_{2} \lambda_{2}}^{\prime}$.

From (B78), (B82), and (B86) we have
(1) $\sigma_{z z}^{\prime \prime}=\sigma_{z z}^{\prime}, \quad \sigma_{\varphi \varphi}^{\prime \prime}=\sigma_{\varphi \varphi}^{\prime}, \quad \sigma_{z \varphi}^{\prime \prime}=\sigma_{z \varphi}^{\prime}$.

Dividing (B84) by (B76) we obtain
(II) $\mathrm{b}^{\prime \prime}=\frac{1}{\mathrm{r}^{\prime}-1}$.

Multiplying (B75) by $r^{\prime}$, and subtracting the resulting equation from (B83) we have (B87) $K^{\prime}\left(b^{\prime}, r\right)\left[\left(1+b^{\prime}\right) b^{\prime}-r^{\prime} b^{\Omega}\right] \sigma_{\lambda_{1} \lambda_{1}}^{\prime}=K\left(b^{\prime \prime}, r^{\prime \prime}\right)\left[r^{\prime \prime}-\frac{1+b^{\prime \prime}}{b^{\prime \prime}}\right] \sigma_{\omega_{1} \omega_{1}}^{\prime \prime}$.

Multiplying (B83) by $r^{\prime}$, and subtracting the resulting equation from (B79) we have (B88) $K^{\prime}\left(b^{\prime}, r\right)\left[(1+b)^{2}-r^{\prime}\left(1+b^{\prime}\right) b\right] \sigma_{\lambda_{1} \lambda_{1}}^{\prime}=K\left(b^{\prime \prime}, r^{\prime \prime}\right)\left[r^{\prime 2}-r^{\prime \prime} \frac{1+b^{\prime \prime}}{b^{\prime \prime}}\right] \sigma_{\omega_{1} \omega_{1}}^{\prime \prime}$.
Dividing (B88) by (B87), assuming $\sigma_{\omega 1 \omega 1}$ and $\sigma_{\lambda 1 \lambda 1} \neq 0$, and thus excluding the pair of models ( $\mathrm{W} 1^{*} \mathrm{~L} 0^{*}$, $\mathrm{W} 0^{*} \mathrm{~L} 1^{*}$ ) from the proof, we obtain (III) $\mathrm{r}^{\prime \prime}=\frac{\left(1+\mathrm{b}^{\prime}\right)^{2}-\mathrm{r}^{\prime}\left(1+\mathrm{b}^{\prime}\right) \mathrm{b}^{\prime}}{\left(1+\mathrm{b}^{\prime}\right) \mathrm{b}^{\prime}-\mathrm{r}^{\prime} \mathrm{b}^{\prime 2}}=\frac{1+\mathrm{b}^{\prime}}{\mathrm{b}^{\prime}}$.

From (B76) we obtain
(IV) $\sigma_{\lambda_{1} \lambda_{2}}^{\prime \prime}=\frac{K\left(b^{\prime}, r\right)}{K\left[b^{\prime \prime}\left(r^{\prime}\right), r^{\prime \prime}\left(b^{\prime}\right)\right] b^{\prime \prime}\left(r^{\prime}\right)^{2}} \sigma_{\omega_{1} \omega_{2}}^{\prime}=\frac{1}{b^{2}} \sigma_{\omega_{1} \omega_{2}}^{\prime}$.

From (B87) we obtain

$$
\text { (v) } \sigma_{\omega_{1} \omega_{1}}^{\prime \prime}=\frac{K\left(b^{\prime}, r^{\prime}\right)}{K\left[b^{\prime \prime}\left(r^{\prime}\right) r^{\prime \prime}\left(b^{\prime}\right)\right]} \frac{\left(1+b^{\prime}\right) b^{\prime}-r^{\prime} b^{\prime 2}}{r^{\prime \prime}(b)-\frac{1+b^{\prime \prime}\left(r^{\prime}\right)}{b^{\prime \prime}\left(r^{\prime}\right)}} \sigma_{\lambda_{1} \lambda_{1}}^{\prime}=\frac{1}{\left(1-r^{\prime}\right)^{2}} \sigma_{\lambda_{1} \lambda_{1}}^{\prime}
$$

From (B85) and (V) we obtain

$$
\text { (VI) } \sigma_{\lambda_{1} \lambda_{1}}^{\prime \prime}=\frac{K\left(b^{\prime}, \mathbf{r}\right)}{K\left[b^{\prime \prime}\left(r^{\prime}\right), r^{\prime \prime}\left(b^{\prime}\right)\right]\left(b^{\prime \prime}\left(r^{\prime}\right)\right)^{2}}\left[\sigma_{\omega_{1} \omega_{1}}^{\prime}+b^{2} \sigma_{\lambda_{1} \lambda_{1}}^{\prime}\right]-\frac{\sigma_{\omega_{1} \omega_{1}}^{\prime \prime}\left(\mathbf{b}^{\prime}, \mathbf{r}^{\prime}, \sigma_{\lambda_{1} \lambda_{1}}^{\prime}\right)}{\left(b^{\prime \prime}\left(\mathbf{r}^{\prime}\right)\right)^{2}}=\frac{1}{\mathbf{b}^{2}} \sigma_{\omega_{1} \omega_{1} \dot{\prime}}^{\prime}
$$

Multiplication of (B77) by r', and subtraction of the resulting equation from (B85) gives
(B89) $K^{\prime}\left(b^{\prime},{ }^{\prime}\right)\left[\left(1+b^{\prime}\right) b^{\prime}-r^{\prime} b^{R}\right] \sigma_{\lambda_{2} \lambda_{2}}^{\prime}=K\left(b^{\prime \prime}{ }^{\prime} r^{\prime \prime}\right)\left[r^{\prime \prime}-\frac{1+b^{\prime \prime}}{b^{\prime \prime}}\right] \sigma_{\omega_{2} \omega_{2}}^{\prime \prime}$, from which we obtain (VII) $\sigma_{\omega_{2} \omega_{2}}^{\prime \prime}=\frac{K\left(b^{\prime}, r^{\prime}\right)}{K\left[b^{\prime \prime}\left(r^{\prime}\right), r^{\prime \prime}\left(b^{\prime}\right)\right]} \frac{\left(1+b^{\prime}\right) b^{\prime}-r^{\prime} b^{2}}{r^{\prime \prime}\left(b^{\prime}\right)-\frac{1+b^{\prime \prime}\left(r^{\prime}\right)}{b^{\prime \prime}\left(r^{\prime}\right)}} \sigma_{\lambda_{2} \lambda_{2}}^{\prime}=\frac{1}{\left(1-r^{\prime}\right)^{2}} \sigma_{\lambda_{2} \lambda_{2}}^{\prime}$.

From (B77) and (VII) we, finally, obtain

$$
\text { (VIII) } \begin{aligned}
\sigma_{\lambda_{2} \lambda_{2}}^{\prime \prime} & =\frac{K\left(b^{\prime}, r^{\prime}\right)}{K\left[b^{\prime \prime}\left(r^{\prime}\right), r^{\prime \prime}\left(b^{\prime}\right)\right]} \frac{1}{\left(b^{\prime \prime}\left(r^{\prime}\right)\right)^{2}}\left[\sigma_{\omega_{2} \omega_{2}}^{\prime}+b^{2} \sigma_{\lambda_{2} \lambda_{2}}^{\prime}\right]-\frac{\sigma_{\omega_{2} \omega_{2}}^{\prime \prime}\left(b^{\prime}, r^{\prime}, \sigma_{\lambda_{1} \lambda_{1}}^{\prime}\right)}{\left(b^{\prime \prime}\left(r^{\prime} \gamma\right)^{2}\right.} \\
& =\frac{1}{\mathbf{b}^{2}} \sigma_{\omega_{2} \omega_{2}}^{\prime}
\end{aligned}
$$

Thus we have proved that given an arbitrary set of parameters in $\mathrm{W} 2^{*} \mathrm{~L} 3^{*}$ we can find a corresponding set of parameters in $\mathrm{W} 3^{*} \mathrm{~L} 2^{*}$ which makes the models observationally equivalent.

From II and III we obtain the following relation between the stability parameters d' and d" (cf (2d)) in W3L2 and W2L3, respectively:
(IX)

$$
\mathrm{d}^{\prime \prime}=1+\mathrm{b}^{\prime \prime}\left(1-\mathrm{r}^{\prime \prime}\right)=1+\frac{1}{\left(\mathrm{r}^{\prime}-1\right) \mathbf{b}^{\prime}}=\frac{\mathrm{d}^{\prime}}{\mathrm{d}^{\prime}-1}, \text { or }
$$

(IX) $\quad \mathbf{d}^{\prime}=\frac{\mathbf{d}^{\prime \prime}}{\mathbf{d}^{\prime \prime}-1}$.

Note that (IX) implies that if $0<d^{\prime \prime}<1$, then $\mathrm{d}^{\prime}<0$, and vice versa. Thus assuming (2e), i.e. $0<d<1$, only one of the symmetric models is relevant. That is, within the set of two symmetric models $\left\{\mathrm{Wi}^{*} \mathrm{Lj}^{*}, \mathrm{Wj}^{*} \mathrm{Li}^{*}\right\}$ we can identify the correct model under assumption (2e).

## B.10. Observational equivalence between WiLi ${ }^{\mathbf{I}}$ and $\mathrm{WiLi}^{\mathrm{II}}, \mathbf{i}=\mathbf{2 , 3}$.

A pairwise observational equivalence analogous to that between $\mathrm{Wi}{ }^{*} \mathrm{Lj}{ }^{*}$ and $\mathrm{Wj}^{*} \mathrm{Li}^{*}$ exists between the two solutions of model $\mathrm{WiLi}, \mathrm{i}=2,3$, i.e. between $\mathrm{WiLi}^{\mathrm{I}}$ and WiLi ${ }^{\text {II }}$. Here we restrict ourselves to demonstrate that the parameters of W3L ${ }^{\text {II }}$ are functions of those of W3L3 ${ }^{\mathrm{I}}$. The proof for the two solutions of W2L2 is analogous, but somewhat simpler. Observational equivalence between the two solutions of W3L3 requires that identities analogous to (B72)-(B74) hold. Let $\mathrm{b}^{\mathrm{I}}, \mathrm{r}^{\mathrm{I}}$, etc. denote the values of the parameters in W3L3 $3^{\mathrm{I}}$, and $\mathrm{b}^{\mathrm{II}}, \mathrm{r}^{\mathrm{II}}$ those in W3L3 ${ }^{\text {II }}$. For all possible combinations of $t$ and $s$ we must now have

$$
+\delta_{\phi \Delta}\left[\sigma_{\varphi \varphi}^{I}-o_{\phi \varphi}^{I I}\right]=0,
$$

(B94) $\left[K\left(b^{I}{ }_{2} \mathbf{r}^{I}\right)\left[r^{I} \sigma_{\omega_{1} \omega_{1}}^{I}+\left(1+b^{I}\right) b^{I} \sigma_{\lambda_{1} \lambda_{1}}^{I}\right]-K\left(b^{I I}{ }^{I}{ }^{I}\right)\left[r^{I I} \sigma_{\omega_{1} \omega_{1}}^{I}+\left(1+b^{I I}\right) b^{I I} \sigma_{\lambda_{1} \lambda_{1}}^{I I} \quad\right]\right]$

$$
\begin{aligned}
& +\left[K\left(b^{I} I^{I}\right)\left[r^{I} \sigma_{\omega_{1} \omega_{2}}^{I}+\left(1+b^{I}\right) b^{I} \sigma_{\lambda_{1} \lambda_{2}}^{I}\right]-K\left(b^{I I} r^{I}\right)\left[r^{I I} \sigma_{\omega_{1} \omega_{2}}^{I I}+\left(1+b^{I I}\right) b^{I I} \sigma_{\lambda_{1} \lambda_{2}}^{I I}\right](t+s)\right. \\
& +\left[K\left(b^{I}, r^{I}\right)\left[r^{I} \sigma_{\omega_{2} \omega_{2}}^{I}+\left(1+b^{I}\right) b^{I} \sigma_{\lambda_{2} \lambda_{2}}^{I}\right]-K\left(b^{I I} r^{I I}\right)\left[r^{I I} \sigma_{\omega_{2} \omega_{2}}^{I I}+\left(1+b^{I I}\right) b^{I I} \sigma_{\lambda_{2} \lambda_{2}}^{I I}\right] t s\right. \\
& +\delta_{t \in}\left[\sigma_{\varepsilon \varphi}^{I}-\sigma_{\varepsilon \varphi}^{I}\right]=0 .
\end{aligned}
$$

For (B92)-(B94) to hold as identities relations analogous to (B75)-(B86) must apply. In three of these relations, those corresponding to (B76), (B80), and (B84), some additional terms have to be included. The three enlarged relations are:

(B96) $K\left(b^{I} I^{I}\right)\left[r^{12} \sigma_{\omega_{1} \omega_{2}}^{I}+\left(1+b^{I}\right)^{2} \sigma_{\lambda_{1} \lambda_{2}}^{I}\right]=K\left(b^{I}{ }^{I} I^{I I}\right)\left[r^{\mathbb{I}} \sigma_{\omega_{1} \omega_{2}}^{I I}+\left(1+b^{I}\right)^{2} \sigma_{\lambda_{1} \lambda_{2}}^{I I}\right]$,
(B97) $K\left(b^{I}{ }_{2} r^{I}\right)\left[r^{I} \sigma_{\omega_{1} \omega_{2}}^{I}+\left(1+b^{I}\right) b^{I} \sigma_{\lambda_{1} \lambda_{2}}^{I}\right]=K\left(b^{I I}{ }^{I}{ }^{I I}\right)\left[r^{I I} \sigma_{\omega_{1} \omega_{2}}^{I}+\left(1+b^{I I}\right) b^{I I} \sigma_{\lambda_{1} \lambda_{2}}^{I I}\right]$.
In the remaining equations it suffices to substitute the model notations ${ }^{I}$ and ${ }^{\text {II }}$ for the apostrophes used to designate the two models in (B75)-(B86). It can now easily be shown that when substituting solutions analogous to (I)-(VII), i.e.
(Ia) $\sigma_{z \varepsilon}^{I I}=\sigma_{z \varepsilon}^{I}, \quad \sigma_{\varphi \varphi}^{I I}=\sigma_{\varphi \varphi}^{I}, \quad \sigma_{\varepsilon \varphi}^{I I}=\sigma_{\varepsilon \varphi}^{I}$.
(IIa) $b^{I I}=\frac{1}{\mathbf{r}^{I}-1}$.
(III) $\mathrm{r}^{\text {II }}=\frac{1+\mathrm{b}^{\mathrm{I}}}{\mathrm{b}^{\mathrm{I}}}$.
(IVa) $\sigma_{\lambda_{1} \lambda_{2}}^{I I}=\frac{1}{b^{I 2}} \sigma_{\omega_{1} \omega_{2}}^{I}$.
(Va) $\sigma_{\omega_{1} \omega_{1}}^{I I}=\frac{1}{\left(1-r^{I}\right)^{2}} \sigma_{\lambda_{1} \lambda_{1}}^{I}$.
(V/a) $\sigma_{\lambda_{1} \lambda_{1}}^{I I}=\frac{1}{b^{I 2}} \sigma_{\omega_{1} \omega_{1}}^{I}$
(VIIa) $\sigma_{\omega_{2} \omega_{2}}^{\text {II }}=\frac{1}{\left(1-r^{I}\right)^{2}} \sigma_{\lambda_{2} \lambda_{2}}^{I}$.
(VIIIa) $\sigma_{\lambda_{2} \lambda_{2}}^{\text {II }}=\frac{1}{b^{12}} \sigma_{\omega_{2} \omega_{2}}^{\mathrm{I}}$.
and in addition
(Xa) $\sigma_{\omega_{1} \omega_{2}}^{\mathrm{I}}=\frac{1}{\left(1-\mathrm{r}^{\mathrm{I}}\right)^{2}} \sigma_{\lambda_{1} \lambda_{2}}^{\mathrm{I}}$,
into these relations, in each of them the left hand side turns out to be equal to the right hand side. The two solutions are thus observationally equivalent.

From (IIa) and (IIIa) we obtain, analogous to (IX) and (IX')
(IXa) $\quad d^{I I}=\frac{d^{I}}{d^{I}-1}$
(IXa) $d^{\mathrm{I}}=\frac{\mathrm{d}^{\text {II }}}{\mathrm{d}^{\mathrm{II}}-1}$.
Note that (IXa) implies that if $0<\mathrm{d}^{\mathrm{II}}<1$, then $\mathrm{d}^{\mathrm{I}}<0$, and vice versa. Thus assuming (2e), i.e. $0<d<1$, only one of the two solutions is relevant, which means that the model is identified. This is empirically illustrated in Table 6.

    * Faculty of Law, University of Oslo, Karl Johansgt. 47, N-0162 Oslo 1, Norway.

[^1]:    ${ }^{\text {a }}$ A model is specified by a combination of 3 labels: e.g. model M0W1L1 is a model where there is no correlation of measurement errors, and no trends in the police district effects on crimes and clear-ups.

[^2]:    ${ }^{\text {a }}$ See section 2.4 and Table 1 for definitions of models. The results hold for both M0 and M1. ${ }^{\mathrm{b}} \sigma_{\mathrm{ze}}, \sigma_{\varphi \varphi}$, and $\sigma_{\mathrm{z} \varphi}$ are identified for W3L3 (and for all submodels).
    ${ }^{\mathrm{c}} \mathrm{b}$ is identified.
    ${ }^{\mathrm{d}} \mathrm{r}$ is identified.
    ${ }^{\mathbf{e}}$ If one of the 4 non-identified parameters is given a fixed value, the remaining ones are identified.

[^3]:    ${ }^{2}$ The critical values of skewness and kurtosis can be found in Pearson (1965). A discussion of the present tests of normality is found in White and MacDonald (1980).

[^4]:    ${ }^{\text {a }}$ See section 3 regarding the symmetry between WiLj and $\mathrm{WjLi}(\mathrm{i} \neq \mathrm{j} ; \mathrm{i}=0,1,2,3$ ).
    ${ }^{\mathrm{b}}$ The model is estimated for a fixed value of b , any b would give the same $\chi^{2}$.
    ${ }^{c}$ The model is estimated for a fixed value of $r$, any $r$ would give the same $\chi^{2}$.

[^5]:    ${ }^{\text {a }}$ The equality of the significance probabilities between Tables 4.1 and 4.2 is due to the symmetry between the models WiLj and WjLi, cf Table 3.

[^6]:    ${ }^{\text {a }}$ See Table 1 for definitions of models. Solutions I and II correspond to the two solutions of a second order equation obtained in identifying the model.
    ${ }^{\mathrm{b}}$ Standard errors in parentheses.
    ${ }^{c}$ A priori restriction.

[^7]:    ${ }^{\text {a }}$ See Table 1 for definitions of models. Solutions I and II correspond to the two solutions of a second order equation obtained in identifying the model.
    ${ }^{\mathrm{b}}$ Standard errors in parentheses.
    ${ }^{c}$ A priori restriction.

[^8]:    ${ }^{\text {a }}$ See Table 1 for definitions of models. Only solutions I are included; see Table 6 for solutions II.
    ${ }^{\mathrm{b}}$ Standard errors in parentheses.
    ${ }^{c}$ A priori restriction.

[^9]:    ${ }^{\text {a }}$ The numbers refer to the equations used for identification. $\mathrm{NI}=$ not identifiable.
    ${ }^{\mathrm{b}}$ Identified assuming $0<\mathrm{d}<1$ or \#A=1, cf section 3.
    ${ }^{c}$ The parameters $\sigma_{z \varepsilon}, \sigma_{\phi \varphi}$, and $\sigma_{z \varphi}$ are identified by (B31), (B32), and (B33), respectively.
    ${ }^{d}$ Identified if $b$ is given a fixed value.
    ${ }^{e}$ Identified if $r$ is given a fixed value.
    ${ }^{f}$ Identified if either $b$ or $r$ is given a fixed value.
